IT may be proper to remark, that this PART is intended as a complete treatise of LAND SURVEYING with the CHAIN only; while it forms the elements, and contains preliminary instructions to be observed, when perusing the succeeding Parts to be published.

The object of having proposed this system of Land Surveying and Levelling, is to form an English Treatise, which in systematic order treats of the Theory and Practice of this branch of Mathematical Science, to that extent to which it now should be understood and practised; for although there are several books upon Land Surveying, these are either very much abridged, or filled with methods which should now be obsolete, when we consider the present perfection of Surveying and Drawing Instruments: besides the practice of many Measurers rather show the want of the application of Mathematical knowledge, in a profession which is purely Geometrical.

In the First Section, I have given those Problems and Theorems, the greater part of which I consider absolutely necessary for the practice and knowledge of a Land Surveyor; but of the first, I have not given the demonstrations; because in doing this alone would have almost constituted a volume of itself, without those advantages which will be found in the study of Euclid's Elements, or other similar treatises which are already published.—The Theorems, with their Co-

to the measure of angles upon the circle, and thereby answering to the figure of those instruments, which he will have much occasion to use in practice, than containing all that Mathematical definition, and strictness of demonstration, which is to be found in the Geometrical works referred to; but these will be found some of the most useful in their applications.

The matter composing the Second Section, contains chiefly the rules and applications of Logarithms to Arithmetical Calculations, with appropriate Examples. In the comprehensive Table which is annexed, will be found an improvement in the arrangement of the Proportional Parts, as explained in the text, by which, with very little trouble, or merely inspection, this Table becomes the Logarithms from 1 to 100,000.

The Third Section is titled Land Surveying, because wholly relating to the method and practice of Measuring Land, and Planning therefrom, as done with the Chain only. Among the first articles is Practical Geometry upon the ground, exemplified by several useful Problems.—The description of the Drawing Instruments which follow, are merely those necessary for protracting Plans from chain dimensions; and afterwards to the conclusion, there are exemplified all the cases of measuring and protracting Single Fields, Farms, Roads, &c.; but which is altogether confined to those methods only affording strict verifications: so that rude methods, as by the general use of the Cross Staff, are only noticed as such.

The Fourth or last Section is wholly devoted to SUPERFICIAL EX-TENT or AREAS, and begins with the particular demonstrations and

\* 18

Rules for finding the area of the Square Rectangle, Triangle, Rhomboid, Trapezoid, Polygon, Circle, Degment, and Sector of Circles, and Ellipse; in illustration of all of which I have given eal-culated examples, both by Natural and Logarithm numbers. The finding of the areas of Single Fields, either when measured together, or separately, is exemplified in the same manner, and here I have demonstrated and applied the ratio of Triangles having one common Angle; by which is obtained a method for calculating the area of each field, without measuring them separately. Also is given the different and best methods for calculating the area from a Delineation or Plan, with calculated examples of each, as used in practice. There is likewise added several Tables, which will be found very useful to the practising Land Surveyor.

In the latter part of this Section is given a method, which in its application I presume is NEW, for finding the product of any two numbers, from a Table of Square numbers, without multiplication; it will also find the sum of the product of any number of pairs of multipliers by the same means, whereby it is more peculiarly applicable to find the area, either severally or collectively, from any number of dimensions which are of Triangles and Rhomboids, or all other figures of which the area is the result of multiplication. This method avoids the constant liability of error in many a tual multiplications of natural numbers, for Addition and Subtraction are the only operations necessary; and is much more expeditious than Logarithms, by avoiding the necessity of finding the product of each pair of multipliers, before the whole sum when only desired can be known.

Throughout the whole of this Part, I have endeavoured to explain the Theory of Land Surveying with the Chain only, without references

to other Geometrical works, but only to the Problems and Theorems in this, by which the learner may gain a competent and correct knowledge of both Theory and Practice within the same volume. It will also be observed, besides the Problems and Theorems under Practical Geometry, others are given where found to be particularly applicable, as in Articles 48 and 50, by which the several uses as applied to Surveying, are directly shewn in Practical Examples, and which will be continued throughout the succeeding Sections to be published.

P. FLEMING.

## SYSTEM

OF

## LAND SURVEYING.

### PRACTICAL GEOMETRY.

GEOMETRY is the Science which discovers the relations and properties of that representation of Magnitude and Extension, which we name figure. The demonstrations of Geometry being derived from the most simple and natural conceptions, are such as afford the clearest evidence to the most intricate propositions, whence it becomes a boundary between truth and uncertainty, in all objects to which it is applicable. The applications of Geometry are so various, that there is almost no Art or Science but of which it is either the basis, or can be made subservient to discover its elements, and if any new effect be discovered, this generally will develope the principle or cause. Astronomy, Navigation, and Geography we know are wholly dependent upon Geometry; and Architecture, Sculpture and Painting, have their rules from its demonstrations: also, in constructing the maps of countries, fortresses and canals, both the Military and Civil Engineer require Geometry; and Land Surveying and Levelling, as constituting the first and necessary operations of the last professions, are its most direct applications.

#### PLATE I.

#### Definitions.

- 1. A point is that which marks position, but not magnitude.
- 2. A line is length without breadth.
- 8. Lines are either straight or curved.
- 4. A straight or right line, lies all in the same direction, between its extreme points, as A.
- 5. A curve line is that of which not any two adjoining portions of it together, is a straight line, as B.
- 6. Lines are said to be parallel, when all the distances between their opposite or corresponding parts keep the same, however far they may be produced, as C.
- 7. Oblique lines are those in which all the distances between their corresponding parts keep not the same when produced, as D.
- 8. An angle is formed by two lines divergent from the same point, as A B and A C, which is usually expressed the angle B A C, as Fig. 1.
- 9. A right angle is that which is equal to either of the two adjacent angles made equal to each other, by a straight line meeting another between its extremities, as DAB, or BAC, Fig. 2.
- 10. An acute angle is a divergence less than that of a right angle, as E A C, Fig. 2.
- 11. An obluse angle is a divergence greater than that of a right angle, as DAE, Fig. 2.
- 12. A perpendicular is a line meeting another and making a divergence with that line equal to a right angle, as A B is perpendicular to A C, Fig. 2.
- 13. A triangle is a plane surface contained by three straight lines; and has its names from the relations of its sides and angles; for if

all the sides are equal, it is called equilateral, as Fig. 3; if two isoceles, as Fig. 4; and if all unequal is scalene, as Fig. 5; also is containing a right angle is right angled, as Fig. 6; or an obtuse angled, as Fig. 4; and if all acute is acute angled, as Fig. 3.

- 14. Any side of a triangle may be called the base, and the angular point opposite, is the vertex; but of a right angled triangle, the side opposite the right angle is the hypothenusc.
  - 15. The angle at the vertex is called the vertical angle.
- 16. A quadrilateral figure is contained by four straight lines; but is denominated from the relation of its sides and angles; for if the sides and angles are equal, it is a square, as Fig. 7; if the opposite sides are equal, and all the angles equal, it is a rectangle, as Fig. 8; if the sides are equal, and the opposite angles only equal, it is a rhombus, as Fig. 9; if opposite sides and angles are only equal, a rhomboid, as Fig. 10; if two of its sides are parallel, and the other two equal, it is a trapezium, as Fig. 11; and if two of the sides are parallel, but all unequal, it is a trapezoid, as Fig. 12.

#### PLATE II.

- 17. A diagonal of a quadrilateral figure, is a straight line, which joins the opposite angular points, as  $\Lambda$  B, Fig. 13.
- 18. Plane figures having more than four sides, are named polygons, and have their names from the number of their sides or angles; as, a polygon of five sides is a pentagon, a hexagon six, a heptagon seven, an octagon eight, &c.; and a polygon is said to be regular, if its sides are all equal, but if unequal, irregular.
- 19. The boundary of any right lined figure is called the perimeter.
  - 20. A circle is a plane figure, contained within a curved line, which

is called the circumference, every point in which is equally distant from a certain point within, named the centre, as Fig. 14.

- 21. The radius of a circle is the distance from the centre to the circumference, as C D.
- 22. The diameter of a circle is equal to twice the radius, or a straight line passing through the centre, and terminating on both sides by the circumference, as A B.
- 23. An arc of a circle is any portion of the circumference, as D E B.
- 24. A chord is a straight line joining the extremities of an arc, as D B.
- 25. A segment is that part of a circle which is bounded by an arc and its chord, such as D E B, and D B.
- 26. The half of the circle is called a semicircle, as F A G, and the fourth part a quadrant, as A C G.
- 27. A sector is any part of the circle bounded by an arc, and radii joining the extremities of that arc and the centre, as D E B C.
- 28. Every arc is the *measure* of the angle or divergence of the radii which joins its extremities to the centre, by being compared to the whole circumference, as D E B is of the angle D C B.
- 29. The altitude of a figure is a perpendicular falling upon the base, or on it produced, from the remotest point opposite.
- 30. Figures are said to be equal, when their corresponding parts coincide, and equivalent, when they contain the same measure.
  - 31. Lines are said to intersect when crossing each other.

### PROBLEMS.

#### PROBLEM I.

The three sides D E.F. being given to construct a triangle.

DRAW A B equal D, and upon the centre A with the distance E, describe a circle. Describe another circle from the centre B, with the distance F meeting the former in C.—Draw A C and B C, and A B C is the triangle.

#### PROBLEM II.

To biscct a given angle E C F.

At equal distances A and B from the angular point C as centres, describe two arcs of the same radius, intersecting at D.—Draw C D and the angle is divided into two equal angles.

#### PROBLEM III.

To make one angle equal to another.

Upon A, the given angular point, with any radius describe an arc, cutting the two sides in B and C: with the same radius describe another arc, E F, from the point D, and from any point E, with the distance B C, intersect it in F.—Draw D E and D F, and the angle F D E is equal to the angle B A C.

#### PROBLEM IV.

To draw a perpendicular to a given point in a straight line.

FROM the given point A of the straight line, make B and C equally distant, and upon these points, as centres, describe arcs of the same radius, intersecting each other at D.—Then draw DA, which is a perpendicular to BC.

#### PROBLEM V.

To draw a perpendicular from one extremity of a line.

TAKE any point C for a centre opposite the line, and upon the same side to which, the perpendicular is to be drawn, and describe with the radius C B the circle A B D, and draw the diameter A C D.—Join D and B, and D B will be the perpendicular required.

#### PROBLEM VI.

To draw a perpendicular from a given point without a straight fine

Upon the given point A as a centre, with any radius cut the straight line in B and C, and from the points B and C, with equal radius make an intersection D,—Draw A D fill it meet the straight line in E, and A E is a perpendicular to B C.

#### PROBLEM VII.

To bisect a straight line.

FROM A and B, the extremities of the straight line, describe arcs making intersections with each other in C and D.—Draw C D, and its intersection with A B, divides the straight line into two equal parts.

#### PROBLEM VIII.

Through a given point C, to draw a line parallel to a given straight line A B.

From any point D, as a centre, in the line A B, describe the arc C E, and from C, with the same radius describe the arc D E.—Make D F equal to E C, and through C and F draw C F, which is the parallel required.

#### PROBLEM IX.

Upon a straight line A B, to construct a square.

Usen A and B, with the radius AB, describe the arcs AC and BD, intersecting at E, and bisect BE in F.—Make ED and EC each equal to EF, and join AD, DC, and BC, which will be a complete square.

#### PROBLEM X.

To divide a straight line A B, into any number of equal parts.

From the extremity A of the given line A B, draw A C at any acute angle, and B D parallel to A C.—Repeat upon A C and B D, from A and B, any convenient distance, the number of times the division is required: join A C and B D, by drawing lines between the opposite and corresponding points, and the same number of intersections will be made upon A B, equally distant from each other.

#### PROBLEM XI.

Two right lines A B and B C being given, to find a mean proportional.

Join A B and B C in one straight line, and bisect i' in D; describe the semicircle A E C, and erect the perpendicula B I, which is a mean proportional to A B and BC, or A B: B E:: B L: B C.

#### PROBLEM XIL

To find a third proportional to two given lines A B and B C.

Upon the extremity of A B draw B C perpendicular; also draw the hypothenuse A C, and bisect it in D, with the perpendicular D E: then upon E, with the distance A, describe the arc A C F, and produce A B to F.—B F is a third proportional to the lines A B and B C; or, A B: B C:: B C: B F.

### PROBLEM XIII.

To find a fourth proportional to three given lines a b, b c, and a d.

MAKE A B equal to the first, and A D equal to the third, and from B, the extremity of the first, draw B C equal to the second, at any convenient angle to A B; also, through the point C, draw A C produced to E.—Draw D E parallel to B C, meeting A C in E, and D E is the fourth proportional; or, A B:BC::AD: D E, and A C:CB::AE:ED.

#### PROBLEM XIV.

The side of a polygon being given, to describe the polygon to any number of sides whatever.

245 4

Oron one extreme of the given side A B, describe a semicircle of any radius, and divide it into the same number of equal parts, as the sides of the required polygon, for instance five. Then draw lines from the centre through the points of division, but omitting the two last; and with the distance of the side A B, from A or B intersect each successively from the next.—Join these intersections, which will complete the polygon.

### PROBLEM XV.

On a given diagonal to describe a square.

BISECT the given diagonal A B, by the perpendicular D E, and upon C, the point of bisection, with the distance A or B, describe the circle A E B D.—Join A E, E B, B D, and D A, and the square is complete.

#### PROBLEM XVI.

\*\*\*\*\*\*\*\*

To inscribe a square in a given triangle.

DRAW the perpendicular C D, and make B E perpendicular and equal to A B; also join E D, and draw F G parallel, and G.H and F I perpendicular to A B.—H G F I will be the inscribed square.

#### PROBLEM XVII.

#### To bisect the drc of a circle A C B.

DRAW the chord A B, and bisect it in the point D, by a perpendicular produced to C, and the arc A C is equal to the arc B C.

#### PROBLEM XVIII.

Given an isoceles triangle A B C, to construct another on the same base but with half the verticle angle.

BISECT A B in the point E; join E C, which produce till C D be equal to C A or C B, and draw A D and D B.—A D B is the isoceles triangle required.

#### PROBLEM XIX.

Given an arc A D B, to find the centre, and complete the circle.

DRAW the chord of the given arc A B, and bisect it by the perpendicular D C; join A D, and from A draw A C, making an angle D A C. equal to A D C.—The intersection C is the centre of the circle required.

#### PROBLEM XX.

. To draw a tangent B D, to a given circle through a given point A.

From the given point A, draw the radius A C, and perpendicular to A C draw B D through the point A.—The straight line B A D is the tangent.

#### PROBLEM XXI.

A tangent line B D being given, to find the point A where it touches the circle.

TAKE any point E on the tangent B D, and from E to the centre draw E C: bisect E C in F, and with the radius F C or F E describe the semicircle C A E, cutting the tangent and semicircle in A, which is the point required.

#### PROBLEM XXII.

Through any three points ABC, to describe the circumference of a circle.

Join the three given points A B and C, and draw perpendiculars bisecting the lines A B and B C, produced till they meet in the point D, which is the centre of the circle required.

#### PROBLEM XXIII.

In a given circle A B D, to describe three equal circles, which shall touch one another, and also the periphery of the given circle.

FROM the centre C, bisect the circle by the right lines C A, C B, and C D: join A D, and produce C D till D G be equal to the half of A D; draw A G, and, parallel to it, D E meeting C A in E: make B F and D H each equal to A E, and upon E, F, and H, as centres, describe the circles through A, B, and D, which will touch one another.

In the same manner may any number of equal circles be made to touch one another within a given circle, by first dividing its circumference into the same number of equal parts as that of the circles required.

#### PROBLEM XXIV.

On a given straight line A B, to describe the segment of a circle which shall contain a given angle C.

DRAW A D, making an angle B A D equal to C, erect A E perpendicular to A D, make E F to bisect A B at right angles and meeting A E in E, and from this point as a centre, and with the distance E A, describe the required segment A G B.

If the angle be a right one, the segment is a semicircle described upon A B.

#### PROBLEM XXV.

Three points being given A B C, to find a fourth P to which, if lines be drawn from the three former, shall be in the ratio of three given lines respectively.

Join the three given points, and make A F equal to a, and A I equal to c; also make the angle A F G and A I K equal, each, to A C B, and from the centres F and G, with the radii b and A K, respectively, describe two arcs intersecting in H: then draw H F and H A, and draw B P to make the angle A B P equal to the angle A H F.—Produce A H, meeting B P in P, which is the point required.

#### PROBLEM XXVI.

\*\*\*\*\*\*\*

To describe a triangle A B C, similar to a giver one, A N M, so that three lines may be drawn from its angular points to another point, which shall be equal to three given lines respectively.

LET A K, A F, and A D be the given lines: draw D E and K G, making the angles A D E and A K G, each equal to the given angle A N M, and intersecting A N in E and G. From D and E as centres, with the distance A F and A G, describe two arcs intersecting in H: draw A H and make A P equal to A D, and from the point P, with the distances A F and A K, respectively cut A M and A N in the points B and C.—Join P B and P C, and A B C is the triangle required.

#### PROBLEM XXVII.

Given the diagonals BE and AD, and two opposite sides AB and DE and the angle made by the inclination of the given sides to each other; to construct a trapezium.

MAKE A B upon any line A C equal to one of the given sides, and make the angle C B G equal to the given angle: draw B G equal to the other given side, and upon A and G, as centres, with the respective lengths of the given diagonals, describe arcs intersecting each other at D.—Make D E equal and parallel to G B, and join D B and E A, and A B D E will be the trapezium required.

#### PROBLEM XXVIII.

To draw from a given point \(\lambda\), is the circumference of a given circle \(\text{A H D}\), a given straight as I ough the circle, so that it shall be cut in any given ratio by the circumference

DRAW the given line A b through any point H of the circle, and divide it in I, to the given ratio; also draw indefinitely another line, A E, at any angle to A B. Produce A B, so as to make H C to A II, and also D L to A D, respectively, in the ratio of B I to I A: then, through the points C, E, and A, describe the circl C L A, and upon A, with the distance A B, cut it in the point I.—Join A L, which is equal to A B, and is cut in the given ratio by the circumference of the given circle A H D F, in the point K.

#### ANOTHER METHOD.

Find the centre M of the given circle, and from A, through M, draw AO, indefinitely cutting the circumference in N: make ON to NA, as BI is to IA, and bisect OA in the point P, which is the centre of the circle CEA.

#### PROBLEM XXIX.

----

Given two concentric circles, BHC and IGK, and the ratio of the two parts of a straight line, the one intercepted between a given point A, in the innermost circle and its circumference, and the other part between the circumference of both the circles, to find the line and its position.

DRAW B C through the given point A and the centre of the concentric circles, and divide A B in D, and A C in E, so that A E is to E C, and A D is to D B. in the same ratio of the parts of the straight line; then bisect D E in the point F, and upon F as a centre, with the distance F D or F E, cut the circumference of the inner circle in G, and through G draw A H, which is the line and its position.

#### PROBLEM XXX.

Given three concentric circles H I G, C L F, and B K E, and the ratio of the two extreme segments of a straight line, the one intercepted be-

tween a given point A in the innermost circle and its circumference, and the other between the second and outerntost circle, to find the wranget line and its position, and the ratio of the middle portion which between the first and second circumference.

DRAW OP through the given point A and the centre of the circles, and make CD to AB, and FM to AE, in the same ratio of the given segments; then bisect DM in the point N, and with the distance ND or NM, cut the circumference of the outer circle in I.—, Draw AI, and make LQ to AK, as CD is to AB; or also in the ratio of the segments: again, with the distance NQ, cut the circle HIG in T.—Join AT, which is the line, and SH the middle segment extremely near.

# **PROBLEMS**

----

# USEFUL FOR DRAWING THE PARTS OF LARGE FIGURES.

#### PROBLEM XXXI.

Three points A, B, and C of an arc being given, to find a fourth D without these points, which likewise shall be in the circumference of the circle of that arc.

FROM A, through the points B and C, draw indefinitely the lines A B and A C, and with any radius describe the arc E G: then make F G equal to E F, and through G draw A G towards D.—Upon C, with the distance C B, cut A G in D, which is the point required.

### PROBLEM XXXII.

Three points of an arc A, B, and C being given, to find a number of points lying between them, which shall be in that same arc.

FROM A, through the points B and C, draw A B and A F, and with any radius describe an arc cutting A B in D, and A C in F: bisect the arc D F in the point E, and through E draw A H.—Join C B and bisect it in G, and draw G H perpendicular to B C, meeting A E in H, which is in the circumference with A B C. In the same manner may other points be found between B H and H C.

#### PROBLEM XXXIII.

To draw a tangent G B to any arc A B C of a circle through any point B, without using the centre.

FROM B towards C, make B D and D E equal, and draw the chord BE: with the radius B D describe the arc GF, and make D G equal to F D.—Through B draw GB, the tangent required.

#### PROBLEM XXXIV.

The arc A B C being given, and a tangent A D to that arc, to find the point of contact, without using the centre.

FROM any point H, without the arc, and with any radius, cut the arc in the points E and F, and join E F: bisect E F in the point G, and draw G H cutting the arc in B.—Make B I parallel to E F, meeting A D in I, and upon I as a centre, with the radius I B, describe the arc B K A, cutting the tangent and the given arc in A, which is the point of contact.

#### PROBLEM XXXV.

To draw an arc of any radius, the chord and height only being given.

MAKE A B the length of the chord, and D C the height of the arc required: draw C B, which will be the chord of half the arc, and perpendicular to C B draw B E; also make B F perpendicular to A B: then divide D B, C E, and B F, each into any but the same number of equal parts, as 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12. Begin at 1 on B F, with the direction of 1 C, 2 C, 3 C, &c. and cut the lines 1 1, 22, 33, &c. in a, b, c, d, e, f, g, h, i, k, which points will be in the circumference of the circle, and B a, b c, &c. C is half of the arc. By doing the same on the other half of the chord A D, the whole arc A C B-may be drawn.

#### PROBLEM XXXVI.

74°+

Given the radius of a circle, to draw any portion of its circumference D I, without using the centre.

or a fourth of the given radius of the required arc, describe the circle AB, and draw, indefinitely, any number of lines AD, AE, AF, AG, AH, and AI, cutting the circle AB in the points a, b, c, d, c, f, g: also make aD, bE, cF, &c. each respectively equal to as many times of aA, bA, cA, as the diameter AB is in the given radius of the arc: that is, if AB is made equal to half the radius of the given arc, aD is to be equal twice aA, bE twice bA, &c.: then through the points D, E, F, G, H, I, draw the arc required.

#### PROBLEM XXXVII.

Given three points A, B, and C, to draw a line from any one of them towards the centre of the arc which the position of these points describe.

Join AB, AC, and BC, and draw CD perpendicular to BC: make the angle BAE equal to the angle ACD, and AE is the line which will pass through the centre of the arc. But if the line is to be drawn from B, produce AB and AC to any distance G and H, and make the angle GBF equal to the angle HCD, and BF is the line required.

#### PROBLEM XXXVIII.

A point B and a straight line A C being given in position, to describe a circle which shall pass through that point and the extremity A of the given line, but whose centre shall be upon that line.

Join A and B, and bisect A B in the point D, by the perpendicular D E meeting A C in E: upon E as a centre, with the distance E A or E B, describe the circle A B F, which is that required.

#### PROBLEM XXXIX.

Two points A and B, and a straight line C D being given in position, to draw a circle which shall pass through the given points, but whose centre shall be upon the given line.

Join A and B, and bisect A B in E, by the perpendicular E F, meeting C D in F.—Upon F as a centre, with the distance F A or F B, describe the circle A B G.

#### PROBLEM XL.

Three points A, B, and C of an arc being given, to complete the arc without using the centre.

From any of the given points, as A, draw A D in the direction of the centre, and from any point E in A D, draw E B or E C: divide E A and E C or E B, each into any number of equal parts, for instance, three; then through any of the corresponding divisions, as 1, 1, describe a circle, having its centre in the line A D, and from E draw any number of lines, as E f, E g, E h, &c. cutting the circle in a, a, a, &c. and passing between the points A, B, C.—Make a b, a c, a d, a e, a f, &c. each equal to the number of times of a E, as E 1 is in 1 C or 1 A, and draw a line through b, c, a, e, f, g, &c. which is the arc required.

#### PROBLEM XLI.

To find the length of any arc A C B of a circle.

DRAW indefinitely the chord A B, and bisect the arc A C B at C, and join A C.—Make A B equal to twice A C, and D E equal to one third of B D: then will A E be equal to the length of the arc A C B.

#### PROBLEM XLII.

Three points A B C being given, lying in the circumference of a circle, and a fourth point D, to find another F, so that a circle passing through F D, and any given point, as B, of the given circumference, shall only touch it at that point.

DRAW B E, bearing upon the centre of the circle, and from D. D. D. F. perpendicular to B E.—Make G F equal to D G, and F is the point required.

#### PROBLEM XLIII.

Three points A, B, and C of a circle being given, and a fourth point D within or without that circle, to find other two points which, with the fourth, will describe a circle concentric to the three given points.

DRAW from any two of the three given points, as A and C, the lines A F and C E, tending to the centre, and upon any point G of the line A F, with the distance G D, describe the circle D F I: also upon H any point in C E, with the distance H D from the centre H, describe the circle D K E: then from D draw D I perpendicular to A F, and D K perpendicular to C E, meeting the respective circles in I and K, which are the two points required.

#### PROBLEM XLIV.

\*\*\*\*\*\*\*

Two lines A B and C D, bearing upon the same distant point, and also a point E in one of them being given, to find two other points, one of which is to be in the other A B, and both lying in the circumference of a circle passing through E, and whose centre is the point of meeting of A B and C D.

DRAW E F perpendicular to A B, and make G F equal to E G,

and F is the point required without A B: from F to any point H in CD, draw F H, which bisect in I; also draw I K parallel to F E, and bisect it in L, and from L draw L D perpendicular to I K, meeting C D in D: again, from F to any point M in A B, draw F M, which bisect in N; and from N, with the distance D I or D K, cut A B in B: upon this point as a centre, with the same radius N B, describe the arc N O, cutting A B in O.—Make O P equal to M O, and P is the other point which is in the line A B as required.

#### PROBLEM XLV.

Three points A, B, and C being given, to draw from a given fourth point D, a line bearing upon the centre of the arc, described by the given position of three points.

DRAW lines A E and C F from any two of the points A and C, tending to the centre, and from A to any point G in C F, draw A G; bisect A G in H, and G C in I, and join H and I: also bisect H I in the point K, and draw K F perpendicular to H I, meeting C F in F: then join A D and C D, and bisect A D in L, and D C in M, and upon L and M as centres, with the distance F H or F I, describe arcs intersecting each other in N.—Through N draw D N, which is the line required.

#### PROBLEM XLVI.

The longest and shortest diameters, viz. A B and C D being given, to

### describe the whole or any portion of an ellipse.

MAKE A F and B G each equal to C E or D E, and upon any of the points 1, 2, 3, 4, &c. in E F; with the distance F E from each respectively, cut D E in 1, 2, 3, 4, &c.: through 1 1, 22, 33, 44, &c. draw indefinitely 1 a, 2 b, 3 c, 4 d, and make 1 a, 2 b, 3 c, 4 d each equal to A F: then draw the curved line A a b c d C, which is a portion of the ellipse required.—In the same manner may the curve be described through C B D A, which will complete the ellipse.

### GEOMETRICAL THEOREMS.

#### AXIOMS.

- 1. EQUAL arcs of the same radius have equal chords; so that if the arc A B C is equal to the arc D E F, the chord A C is equal to the chord D F.
- 2. Parallel lines, however, drawn through a circle, intercept equal arcs upon the circumference; as the arc A B is equal to the arc C D.
- 3. The greater chord in a semicircle subtends the greater arc; as if the chord A B is greater than the chord D E, the arc A C B is greater than the arc D C E.

4. Equal arcs subtend equal angles at the centre in circles of the same radius; as if the arc A B is equal to the arc D E, the angle A C B is equal to the angle D C E.

#### THEOREM I.

If a line C D meet another line A B, the angles A D C and C D B are together equal to two right angles.

DESCRIBE from D the semicircle AECB, and draw ED perpendicular to AB: the arc AC is the measure of the angle ADC, and the arc CB is the measure of the angle CDB: (Def. 28.) also the arcs AE and EB, respectively, are the measures of the right angles ADE and EDB: (Def. 9.) but the arcs AC and CB are together equal to the arcs AE and EB, and consequently the angles ADC and CDE are together equal to two right angles.

Corollary.—Hence the whole circumference of a circle described from the point D of intersecting lines, being double the semicircle A E B, is the measure of four right angles.

#### THEOREM II.

If two right lines A B and C D intersect each other, the opposite angles

C E B and A E D are equal.

upon E as a centre describe the circle ACBD: the angles A and BED are together equal to two right angles, (Theor. 1.) the control of the angles AED are also together equal to two right angles; there is the angles AED and BED together are equal to the angles CED and BED, and consequently the angle AED must be equal to the angle CEB.—In the same manner it may be demonstrated, that the angle AEC must be equal to the angle DEB.

#### THEOREM III

If the right line G F cut other two parallel lines A B and C D, the outward angle G E B is equal to the opposite and inward angle E F K.

LET E G be equal to E F, and draw a third line L M through G parallel to A B, and upon F and E as centres, with the distance F E or E G, describe the arcs E K and G B: because F E is equal to E G, and is parallel to E B, and G F a straight line, the intercepted arcs B G and E K are equal; (Ax. 2.) consequently the angles G E B and E F K are also equal. (Ax. 4.)

Cor.—The alternate angles A E F and E F K are equal, for A E F is equal to G E B. (Theor. 2.)

#### THEOREM IV.

The angle A B C and B A C at the base of an isoceles triangle are equal.

und through C draw D E parallel to A B: the angle A C D is equal to the angle B A C, and the angle A B C is equal to the angle B A C, and the angle A B C is equal to the arg B E, for D E is parallel to A B; (Ax. 2.) therefore the angles A C D and B C E are again, (Ax. 4.) and the angle A B C is equal to the angle B A C.

#### THEOREM V.

The angle C A B at the centre of a circle, is double the angle C D B at the circumference, standing upon the same arc B C of that circumference.

Through A draw D F, and draw D E parallel to A B, the angle A B D is equal to B D E, (Cor. Theor. 3.) and because the angle A B D is equal to A D B, (Theor. 4.) the angle B D E is equal to A D B; but the angle F A B is equal to the angle A D E, (Theor 3.) consequently the angle F A B is double the angle A D B.—In the same manner it may be demonstrated—the angle F A C is double the angle F D C; now taking the angle F A C from the angle F A B, and the angle F D C from the angle F D B, the remaining angle C A B at the centre is double the remaining angle C D B at the circumference. N. B. In applying this demonstration to Fig. 2, instead of taking from, add the angle F A C to the angle F A B, and the angle F D C to the angle F D B, the angle C A B at the centre is double the angle C D B, &c.

Car. 1.—Hence the angle at the circumference standing on the diameter, or a semicircle, is a right angle; but if standing upon less than a

semicircle, is acute, and if upon greater, is obtuse, for this angle is these ured by the half of the subtending arc of the circumscribing circles.

Cor. 2.—Angles at the circumference in the same segment, standing upon the same arc are equal, for the half of the same arc is the measure of each.

#### THEOREM VI.

The three angles A B C, B C A, and C A B of a triangle are equal to two right angles.

DESCRIBE the circumscribing circle, and join the angular points A, B, and C to the centre D: the angle BDC is double the angle BAC, the angle BDA is double the angle BCA, and the angle ADC is double the angle ABC; (Theor. 5.) but the arcs measuring the angles BDA, BDC, and ADC are together equal to the whole circumference, or four right angles: (Cor. Theor. 1.) consequently the angles BAC, BCA, and ABC together are equal to half of the circumference, or two right angles.

Cor. 1.—Hence triangles having equal sides must be equiangular, and in every respect equal, for the half of the arcs intercepted by the corresponding sides upon the same circumscribing circle, are equal. (Ax. 4.)

Cor. 2.—Triangles which have two of their sides and the included angle equal, are equal to one another; because the arcs subtending the given angle upon the same circumscribing circle, are each equal to double the measure of that angle, and consequently the chords or third, sides must be likewise equal. (Ax. 1.)

Cor. 3.—Also, equiangular triangles having one corresponding side

ponding emples are equal upon circles of the same radius. (Ax. 1.)

#### THEOREM VII.

In every right lined triangle A B C, the greater angle A B C is opposite the greater side A C

points A, B, and C to the centre D: the angle A D C is double the angle A B C, the angle A D B is double the angle A C B, and the angle B D C is double the angle B A C; (Theor. 5.) but the arc A C is the measure of the angle A D C, and is greater than either of the arcs A B or B C, for A B C is the greater angle; (Theor. 5. Cor. 1.) therefore the chord A C is greater than either of the chords A B or B C, (Ax. 3.) and the angle A B C being measured by the half of A D C, is consequently greater than either of the angles B A C or B C A, and is opposite the greater side A C.

#### THEOREM VIII.

Parallelograms A C D B, E C D F, and E G H F, standing upon the same base C D, or on equal bases C D, G H, and between the same parallels, are equivalent.

BECAUSE C A is parallel to D B, and G E parallel to H F; A B,

E F, and C D are equal: also A E is equal to B F, therefore the triangles A C E and B D F are equivalent: (Theor. 6. Cor. 2) from each of the triangles A C E and B D F take the triangle B E I, and the remaining trapeziums A B I C and E I F D are also equivalent. To each of the trapeziums A B I C and E I F D add the triangle. C I D, then the parallelogram A B C D is equivalent to the parallelogram E B D G, and standing upon the same base C D.

#### THEOREM IX.

A triangle ABC is the half of a parallelogram ABCD, when they stand upon the same base AB, and are between the same parallels AB and CD.

For A C is equal to B D, and A B to C D, and C B is common to the triangles A B C and C D B, which are therefore equal: but the parallelogram A B C D is equivalent to the parallelogram A B C D: (Theor. 8.) consequently the triangle A B C is equal to the half of the parallelogram A B C D.

Cor. 1.—Hence every parallelogram is besected by its diagonal.

Cor. 2.—Triangles upon the same base, or on equal bases, and of the same altitude, are equivalent.

#### THEOREM X.

The square CAED described upon the hypothenuse of a right angled

Friangle, is equivalent to the squares AIHB and CFGB of the two sides.

Upon the sides CD and AE describe the triangles CFD and AI The interest and equivalent to ABC, by making CF and IE each equal . 45 B C, and F D and A I each equal to A,B: produce A B and F D until they meet in G, and also C B meeting I E in H; also draw EK parallel to AIE, and make BM equal to IH, and LM , perallel to A B: then C G is a square described upon C B, for the angles DFC, FCB, and CBG are right angles, and CF is equal to CB; also AH is a square upon AB, for the angles HI A, I A B, and A B H are right angles, and A I is equal to A B. (Def. 16.) The polygon A L M O is equal to the square A H, for the trapezium A B M L is similar and equivalent to the trapezium A I HO, and the triangle A BO is common. Again, the triangle AKE is half of the rectangle AE, and is equivalent to AIE or ABC, and KE is equal to AB; the angle KEN is equal to the angle BAC, and the angles EKN and ABO are right angles; therefore the triangle KEN is similar and equivalent to ABO, (Theor. 6. Cor. 3.) and the trapezium ALMB and the triangle KEN is equivalent to the square AIHB: because DG is parallel to CM, D N is parallel to C L, and N G is parallel to I M, the triangle D G N and C L M are similar; but they are also equivalent, for E N is equal to A O, which is equal to A L, and D N must be equal to C L: (Cor. 3. Theor. 6.) therefore the polygon C B N D and the triangles A K E and C L M are equivalent to the square C G, for the triangle A K E is equal to C F D, and G L M is equal to D N G, and consequently the polygon C B N D, and the trapezium A L M B. together with the triangles AKE, EKN, and CLM are equivalent to the square ACDE, or to the squares AIHB and CBGF together.

# THEOREM XI.

If a right line A B be divided into any two parts A C, C B, then will the square of the whole line A B be equal to the sum of the squares of the parts A C and C B, together with twice the rectangle of the parts.

Upon A B construct the square ABDE, and make BG equal to AC, and draw CH parallel to BD, and GI parallel to ED: because AF is to the square AC, and FD is to the square of CB, and CG and IH are each equal to the rectangle of AC and CB:—the squares AF and FD together, with the rectangles IH and CG, make up the square AD.

#### THEOREM XII.

If a straight line A B touches a circle, the straight line C D drawn from the centre to the point of contact shall be perpendicular to the line touching the circle.

Through the centre C draw E F parallel to A B, and from E and F draw F A and F B perpendicular to E F or A B—because E F and A B are parallel, E A and F B are equal, (Def. 6.) and are the shortest lines which can possibly be drawn from the points E and F to A B: but A B touches the circumference only at the point D, therefore D is the nearest point of A B to the centre C; and C D, which is equal to the radius, must be also the shortest line which can be drawn from C to the line A B: consequently C D is equal to E A or F B, and is likewise a perpendicular to A B.

#### THEOREM XIII.

If a straight line E F touches a circle, and from the point of contact B a straight line B D be drawn cutting the circle, the angle D B F made by this line with the line E F, shall be equal to the angle B A D in the alternate segment of the circle.

DRAW the diameter B A, and join D A; the angles B D A and A B F are right angles, therefore the angles B A D and A B D are together equal to a right angle: (Theor. 6.) but the angles A B D and D B F are also equal to a right angle, (Theor. 12.) consequently the angles B A D and A B D are equal to the angles D B F and A B D. Take the angle A B D from each, and B A D is equal to the angle D B F.—In like manner it may be demonstrated, that the angle C B F is equal to the angle B A C, and generally D B F is equal to the angles B A D or B G D, and C B F is equal to the angle B A C or B H C. (Theor. 5. Cor. 6.)

#### THEOREM XIV.

If two right lines A B and C D intersect each other in a circle, the half of the sum of the intercepted arcs A D and C B measure the angle C E A or B E D.

DRAW D.B; the angles A E D and D E B are equal to two right angles, and the angles D E B, E B D, and E D B are also equal to two right angles; (Theor. 6.) therefore by taking the angle D E D

from each, the angle AED is equal to the angles EBD and EDB: but the angle EDB is measured by the half of the arc CB, and EBD by the half of the arc AD; (Theor, 5. Cor. 2.) consequently the angle AED is measured by half the arc CB, together with half the arc AD.

## PROPORTION.

# EXPLANATION OF SIGNS.

- + PLUS, signifies the addition of the quantities between which it stands, as A+B, that is, B is to be added to A.
- Minus, signifies that the quantities before which it stands are to be subtracted, as A—B, that is, B is to be subtracted from A.
- × Into, signifies that the quantities between which it stands are to be multiplied together, as A×B, is A multiplied by B, and is put in the form A B when each letter expresses a quantity.
- $\div$  Divided by, signifies that the former is to be divided by the latter, as  $A \div B$ , that is, A is to be divided by B. Sometimes the division of quantities is also expressed by placing the divisor below the dividend, as  $\frac{A}{B}$
- = Equal to, signifies that the quantities between which it is placed are equal to each other, as A=B, that is, A is equal to B.

This sign, called a *vinculum*, when placed over quantities, signifies that they are to be taken collectively, as  $\overline{A+B+C} \times E$ , that is. the sum of A, B, and C is to be multiplied by E.

The small integers ', ', ', &c. annexed to quantities, signify, that the quantity is to be multiplied that number of times by itself; as,  $A'=A\times A$ , and is called the square of that quantity, or second power,  $A'=A\times A\times A$ , and is called the cube, or third power, and  $A'=A\times A\times A$ , the biquadrate, or fourth power.

The signs  $\sqrt[3]{}$ ,  $\sqrt[3]{}$ ,  $\sqrt[4]{}$ , &c. placed before any quantity, as  $\sqrt[3]{A}$ , signify that the operation of extracting the root of that power is to be performed, as  $\sqrt[3]{A^2}=A$ , or  $\sqrt[3]{A^3}=A$ , &c.

# DEFINITIONS.

- 1. If magnitudes or quantities be referred to one common standard of measure, the comparison of their respective values is called the *ratio* of these magnitudes. Thus if A is found to equal 5, and B=10, the ratio of A to B is as 5 is to 10.
- 2. If one quantity contain another any number of times, the first is called a *multiple* of the second. Thus B=10 is a multiple of A=5.
- 3. The first term of a ratio is called the *antecedent*, and the second the *consequent*; as in the ratio of A to B, A is the antecedent, and B the consequent. The ordinary expression for the ratio of two quantities, is made by setting the antecedent above the consequent, as  $\frac{A}{R}$ .
- 4. The multiple of a ratio is the product of each of the terms by the same quantity; as  $\frac{A}{B}$  multiplied by C will stand  $\frac{A \times C}{B \times C}$ . The product of the antecedent becomes a new antecedent, and the product of the consequent a new consequent, having the same ratio to each other;

as 
$$\frac{A}{B} = \frac{2}{2} \frac{A}{B} = \frac{3}{3} \frac{A}{B}$$
 &c.,

- 5. Ratio of equality is when the antecedent is equal to the consequent.
- 6. Four quantities are said to be proportional, which, when compared two and two, are found to have the same ratios; as in the quantities A, B, C, D; A is to B, as C to D, and A is to C, as B to D, or the ratio  $\frac{A}{B} = \frac{C}{D}$  and  $\frac{A}{C} = \frac{B}{D}$ , and the proportion is thus expressed; A:B:: C:D, or A:C::B:D. The first proportion is called direct, for the second term is consequent to the first, and the fourth a consequent to the third; and the second alternate, because the third term is consequent to the first and the fourth a consequent to the second.

#### THEOREM XV.

44

When four quantities a, b, c, d are proportional, the product of the ex-treme a and d is equal to the product of the means b and c.

If a:b::c:d, then  $\frac{a}{b} = \frac{c}{d}$  and  $\frac{a}{b} = \frac{a \times d}{b \times d}$  also  $\frac{c}{a} = \frac{c \times b}{d \times b}$  therefore  $\frac{a \times d}{b \times d} = \frac{c \times b}{d \times b}$  (Def. 4.) this ratio put again in the first form, is  $a \times d:b \times d::c \times b:$ 

 $d \times b$ . Hence since the consequents are equal, the antecedents are equal, and  $a \times d = c \times b$ .

Cor. 1.—If the first term be to the second as the second to the third, that is, as a:b::b:c, the rectangle of the extreme is equal to the square of the mean, or  $a c=b^2$ .

Cor. 2.—If two rectangles are equal, their sides are reciprocally proportional; if the rectangle x is equal to the rectangle z, then ab=cd, and a:c::d:b.

#### THEOREM XVI.

In any plain triangle A B C, the adjoining sides A B, A C, are cut proportionally by a line D E drawn parallel to the other side B C; that is, A D: D B:: A E: E C.

Cor. 1.—Hence, when the sides A B, A C of a triangle are cut proportionally in D and E, the segments A D, A E, and D B, E C of those sides are proportional to the sides; and the line D E joining those sections, is parallel to the other side B C.

('or. 2.—In equiangular triangles, as ADE, ABC, the sides adjacent to the equal angles are proportional, and also the sides opposite the equal angles are proportional.

### THEOREM XVII.

In a right angled triangle, if a perpendicular A D be drawn from the right angle B A C to the base B C, the triangles on each side of it are similar to the whole triangle, and to one another.

BECAUSE the angles A D B and B A C are both right angles; the angle A B D is common to the triangles B A C and A B D, which therefore have the remaining angles B A D and B C A equal, (Theor. 6.) and the triangles B A C and A B D are equiangular.—In like manner it may be demonstrated—the triangle A C D is similar to the triangle B A C, and consequently the triangles A B D, A D C, and B A C are similar.

Cor.—Hence **B** D: A D:: A D: D C, or the perpendicular A D is a mean proportional to the segments upon the base B D and D C; and B D×D C=A D<sup>2</sup>. (Theor. 15. Cor. 1.)

#### THEOREM XVIII.

If two chords A B and C D intersect each other within a circle or without it, by being produced, the rectangle under the segments made by their intersection, and terminated by the circumference, are equal; that is, BE×EA=DE×EC.

Join BC and DA; because the angle DEA and BEC are equal, (Theor. 2.) and the angle CBA and CDA are also equal, the triangle BEC is similar to the triangle DEA; (Theor. 5. Cor. 2.) therefore AE:CE::DE:BE, or BE × AE = DE × CE. (Theor. 15.)

# LEGARITHMS:

LOGARITHMS are a set of artificial numbers, arranged in tables, peculiarly adapted to facilitate the enumeration of natural numbers. Their properties are such, that the sum of the Logarithms corresponding to any two or more natural numbers, answers to the Logarithm of their product. The Logarithm of every number is expressed by one of the indices 0, 1, 2, 3, 4, 5, &c. with decimals annexed to each index. as the Log. of 1 is 0.0000000, of 10 is 1.0000000, of 100 is 2.0000000, of 1000 is 3.0000000, &c. Hence it appears, that the indices of the Logarithms form a series in Arithmetical progression, or have a common difference in each term, and the natural numbers answering to this series are in Geometrical progression, or every term is a certain multiple of the preceding one. In the following system of Logarithms, the numbers corresponding to every different integer of the indices are each a power of 10; for example, the Log. index 2 answers to 100=10°, and 3 answers to 1000=10°, &c. but if this series was changed by assuming the power of any other number corresponding to the same indices, another system of Log. would be formed, having the same peculiar properties as the above: for instance, if we had assumed the Geometrical series of numbers to be the powers of 8, then every different index of the Log. would correspond to a different power of 8; as the Log. index 1 would in this system answer to 8, and the

index 2 to 64=8°, and 8 to 512=8°, &c. so that as any number may be taken in place of 10, there may be an infinite number of different systems of Logarithms.

Since in the following system 0 is the Logarithm of 1, 1 of 10, 2 of 100, and 3 of 1000, the Logarithms of the numbers lying between 1 and 10 must be each greater than 0, and logarithm of these are expressed by decimals of 1; as.

No.	Logarithms.
2	0.8010300
3	0.4771213
4	0.6 <b>02</b> 0600
5	<b>0.698</b> 9700
6	<b>0.778</b> 1513
7	<b>0.8450</b> 980
8	<b>0.9030900</b>
9	0.9542425

The same may be shown of the Logarithms of numbers between 10 and 100, or between 100 and 1000; for those between 10 and 100 must be each greater than 1 and less than 2, and between 100 and 1000 each is greater than 2 and less than 3; as,

No.	Logarithms.	No.	Logarithms.
20	1.3010300	200-	2.3010300
30	1.4771213	300	<b>2.4771213</b>
40	1.6020600	400	2.6020600
50	1.6989700	500	2.6989700
60	1.7781513	600	2.7781513
.70	1.8450980	700	<b>2.845098</b> 0
80	1.9030900 °	800	2.9030900
90	1.9542425	900-	2.954 <b>24</b> 25°

Note.—To those who wish to understand thoroughly the construction of Logarithms, I recommend for their perusal the Introduction to Hutton's Logarithmic Tables.

#### EXPLANATION OF TABLE V.

The first or left-hand column of the first page, which is marked N. contains the natural numbers from 1 to 100, and in the second column, marked L. are the corresponding Logarithms to each number.

The second, and all the remaining pages of this Table, are divided into eleven columns, the first of which is, as before, marked N. containing all the Numbers from 100 to 1000, and the remaining ten, marked 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, contain the corresponding Logarithms of all the numbers from 100 to 10,000.

The indices are not printed with any of the Logarithms, except those Numbers from 1 to 100, but the index of each must always be prefixed when used; it being understood, that the index 2 is to be put before the Tabular Logarithm for all numbers from 100 to 1000, and 3 from 1000 to 10,000, and so on, making the index always one less than the number of integer figures at the Number for which the Logarithm is taken. Also in the same columns the first figure after the index being the same for several lines, is not repeated except in column 0, when it changes, but which, likewise, must be always prefixed to the other figures—thus making every Logarithm of this Table to contain seven places besides the index.

There being a difference between the Logarithm of every different number, the parts of these differences are proportioned for every integer from 1 to 10: they are arranged under the Logarithms of each page, to which they respectively belong, and titled PROPORTIONAL PARTS. This Table has a column N. containing the Numbers, and another D. of the corresponding Differences; but the particular use of it will be better explained in the following examples.

# Examples for finding the Logarithm of any given Number,

- Ex. 1.—The Logarithms of all the Numbers of two places, that is, from 1 to 100, are found in the first page of the Table, in the column L.; thus if that of 16 is wanted, the Logarithm opposite that Number, viz. 1.2041200, is the one required.
- Ex. 2.—To find the Logarithm of a number of three places, as 165. Find in the column N. the No. 165, and opposite, in column 0, is £174839, to which prefix the index 2, and 2,2174839 is the Logarithm required.
- Find the three first tigures vi 276, in column N. and in column 8 the name of the fourth figure is .4+21661, to which prefix the index 3, and 3.4421661 is the Logarithm required.
- Ex. 4.—To find the Log. of a number of five places, as 13458. by Ex. 3, the Logarithm of the first four figures, viz. 1345-1287223. and subtract this Logarat m from the next highest, viz. .1290451. and the difference will be 3228; then take 8 tenths of this difference. or the tenth part of it multiplied by the fifth figure of the given Number, which add to the Logarithm found, as .1287223+2582=.1289805. to which prefix the index 4, and 4.1289805 is the Logarithm required. Instead of subtracting the whole Logarithms from each other for finding the difference, subtract only the last figure of the lower from the last of the higher, and the remainder is the fourth figure of the difference; and in the column N. of the Proportional Parts, find the first figures of the given number, or the nearest number to them, and in the same line in column D. is the three first figures, which prefixed . to the fourth, gives the whole Tabular Difference: as for example, the subtracted last figures of the Logarithms of 1345 and 1346 is and opposite 1347 in column D. of Proportional Parts is 322 making 3228

the same as before. In the same manner the tabular difference of any two Logarithms may always readily be found by inspection.

Ex. 5.—To find the Logarithm of six, seven, and eight places.

First, for six figures, or 154396. By the last example find the Logarithm of the first five figures, viz. 15439, which is .1886192, then in the column N. of the Table of Proportional Parts, find the same number, or the next lowest, and in the same line take out the proportional part 169 in the column of the sixth figure. This added to the Logarithm found, as .1886102+169=5.1886261, is the Logarithm required.

Second, for seven figures, or 1543964. As above find the Logarithm for the first five figures, viz. 15439, and the Proportional Parts for 6 the sixth figure, and for 4 the seventh; of which add to the Logarithm found the whole for the sixth Proportional Part, and the tenth for the seventh: as,

	15439 the	Loga	rithm	of is		188	6191.6
Pro. Part for	6	-	-	-	-	-	169
Pro. Part for	4	-	-	-	-	-	11.2
	1543964					$6.\overline{188}$	6372.

the Logarithm required.

Third, for eight figures, or 15439647. The same operation as before is to be performed for finding the Logarithm of seven figures, and add the hundredth of the Proportional Part for the eighth figure: as

		15439 the	Log	arith	m o	f is			.188	6191.6
Pro. Par	t for	6	-	_			_		-	169
Do.	for	4	-	_		_	_		_	11.2
Do.	for	7		_	-	-		_	-	.1.97
		15439647						7.1	886	373.77

When it happens that the remainder or first figure cut off to the right

hand of the sum of the Logarithm after the Proportional Parts are added, is above 5, the last figure of the Logarithm is to be increased by unity; as in the last example, 7.188637\$,7 will become 7.188637\$.

The Logarithms of Decimal Numbers are found in the same manner as the preceding examples, by considering the Decimals as a whole number: but prefixing the value of the index according to the number of figures in the given integral only: as for example,

No. Decimals.		Logarithms.
1.5489647		0.1886374
15.439647	•	1.1886374
154.39647	•	2.1886374
1543.9647		3.1886374
15489.647	***************************************	4.1886374
154896.47	-	5.1886374
1543964.7		6.1886374

In the case where the number for which the Logarithm is wanted is wholly a Decimal, the index of such becomes negative, and is marked by the sign *minus* over it. If there is no cypher between the first significant integer and the decimal point, the index is  $\overline{1}$ , and if one cypher it is  $\overline{2}$ , and if two cyphers it is  $\overline{3}$ , &c. it being a general rule to make the index for Decimals one more than the number of cyphers between the first significant figure and the decimal point; as,

Decimals.		Logarithms.
.15439647	-	1.1886374
.015439647	*****	2.1886374
.0015439647		3.1886374
.00015439647		4.1886374
.000015439647	•	5.1886374
0000015439647	-	$\overline{6}.1886374$

"i >

Ex. 6.—To find the Logarithm of a fraction, or a mixed number, as #. Reduce the vulgar fraction to a decimal, and find its Logarithm by the preceding examples for whole numbers; or subtract the Logarithm of the denominator from the Logarithm of the numerator, and the remainder will be the Logarithm wanted; as, #=3.125 Logarithm of is 0.4948500, which was required: or,

From the Logarithm of 50 is \_\_\_\_\_ 1.698970 Subtract the Logar. of 16 \_\_\_\_\_ 1.204120 0.494850

If a Valgar Fraction be subjoined to a whole number, the whole expression may be reduced to a fraction, and the Logarithm of it thence found as above; as  $17?=\frac{38}{7}$ ; or the fraction may be transformed into a decimal, and the Logarithm of the whole found as a decimal number; as 17?=17.6: for,

From the Logarithm of 88 — 1.9444827 Subtract the Logar. of 5 — 0.6989700 1.2455127

is the Logarithm of 17%. Also, the Logarithm of 17.6=17% is 1.2455127.

To find the Natural Number answering to any given Logarithm.

Find the first three figures of the given Logarithm after the index, or the three next lowest in column 0, and in the same line seek the given Logarithm, or the next lowest to it, and the number opposite in column N., are the three first figures of the number sought, and the number at the top of the column in which the given Logarithm, or its nearest is found, is the fourth.

If the index of the given Logarithm is 0, 1, or 2, the four figures

thus found, will be partly decimal, as the integral number must be marked off upon the left, according to the index: but if the index is 8, these will be a whole number. If the given Logarithm cannot be exactly found, subtract the next lowest from it, and divide the difference by the tenth parth of the Tabular Difference, (Ex. 4.) and the quotient will be the fifth figure of the number sought. Again, there be a second remainder, seek the five figures already found, or the nearest number to them in column N. of Proportional Parts, and in the same line, seek also the number of the remainder, and the figure at the top of the column in which it is found is the sixth figure: but if this remainder is not exactly found, subtract the next Proportional Part from it, and this third remainder, by annexing a cypher, becomes a number, by which, in like manner, the seventh figure may be found; and if the fourth remainder cannot be exactly found in the same line, subtract the next lowest part from it, and by adding a cypher to the remainder, it becomes also a number, by which the eighth figure is found: as

Ex. 7.—To find the natural number answering to the Logarithm,

	7.1000 <i>3</i> / <del>4</del>	
Next lowest Logarithm of 1563	1883669	
First Remainder	2715	
which divided by the Tabular Difference, as	281.4)2715.0(9	the fifth
figure of the number sought.	25326	
Second Remainder	182.4	

Second Remainder	182.4
6 the first Proportional Part	169
Third Remainder	134
4 the second Proportional Part	112
Fourth Remainder	220
7 the third Proportional Part	197

· Hence the Natural Number found for the Logarithm 7.1886374

when put together is 15450647. The three last figures may be found otherwise thus; after finding the first five figures as above, find the Tabular difference answering to them, (Ex. 4.) and divide the second remainder by it.—Continue this division by adding cyphers, as far as the index of the Logarithm requires it to be made, and the quotient will be the figures sought: as

281)182. (647 the same as before.

# ARITHMETIC BY LOGARITHMS.

#### I. MULTIPLICATION.

ADD together the Logarithms of all the factors, and the sum is the Logarithm of their product.

If the indices are all positive, add to them the number carried from the decimal addition, and the sum is the index of the Logarithmic product: but if both positive and negative, the number carried from the decimal Addition is to be added to the positive indices, and the difference of the positive and negative to be put down for the index of the Logarithmic product with the sign of the greatest.

	, ° '
Ex. 8.—Multiply 26.04 by 6.325.	Ex. 16.—Multiply 2.86, 2.48,
The Log. of 26.04 is 1.4156410	.062 and .002 together.
of 6.325 is 0.8010605	2.36 Log, of is - 0.3729120
Product 164.703 - 2.2167015	2.48 0.3944517
Ex. 9.—Multiply 2.603, 673.4	.062 2.7923917
and .2638 together.	.002 3.3010300
2.603 Log, of is - 0.4154742	Product00072574 4.8607854
673.4 2.8282731	Ex. 11.—Mult. 32684 by 67324.
$.02638 - \overline{2.4212748}$	32684 Log. of is - 4.5143352
Product 46.24045 - 1.6650221	67324 4.8281699
•	Product 2200417610 9.3425051

It is necessary to observe, that the number answering to any given Logarithm found by Table I. is true to eight or nine figures, but cannot be depended on farther; for, by the last example, the true product is 2200417616, so that in this case it is true to the ninth figure. Tables which would give correct answers to more figures, would require the Logarithmic decimal extended to a greater number of places, and hence would be much more voluminous than this

#### II. DIVISION.

From the Logarithmic decimal of the dividend subtract the Logarithmic decimal of the divisor—the remainder will be the Logarithmic decimal of the quotient.

But change the sign of the index of the divisor from plus to minus, or from minus to plus, and the sum of the indices of the same sign, or the difference when of different signs with the sign of the greater, is to be set down for the index of the Logarithm of the quotient.

the index of the divisor when that index is plus, but subtract it when distant, and the index th

##. 22.—Divide 1868 1868.

### 1868 Log. of is 3.1344959

#### 1268 \_\_\_\_\_\_ \$4081196

### 18.—Divide 8462 by 6924.

Divid. 3462 Log. of is 3.5396271

Divis. 6924 \_\_\_\_\_ \$.8403571

.5 \_\_\_\_ 1.6989700

Here the Logarithm of the divisor is positive, and I carried from the decimal being added to its index, and then changed to the negative, the difference between the indices becomes I. Ex. 14.—Divide 28.28 by 344.67.

Divid. 28.23 Log. of is 1.4507109

Divis. 344.67 \_\_\_\_\_\_ 2.5874085

.08179044 \_\_\_\_\_ 2.9133074

Ex. 15.—Divide .6823 by 234.6

Divid. .6828 Log. of is 1.8839754

Divis. 234.6 \_\_\_\_\_\_ 2.4703280

.002915 \_\_\_\_\_ 3.4636474

In this last example, by changing the positive index of the divisor to negative, it becomes of the same sign of the dividend, or both negative, and the sum is 3.

#### III. PROPORTION.

Add the Logarithms of the second and third terms together, and from the sum subtract the Logarithm of the first by the rules of the preceding examples—the remainder will be the Log. of the 4th term.

Ex. 16.—Find a fourth propor-Ex. 17.—Find a fourth proportional to 36.32, 3.648, and 423.6. tional to 2.46, 0.23, and 1.35. As 36.32 Log. of 1.5601458 As 2.46 Log. of 0.3909351 0.5620548 is to 3.648 is to 0.23  $\overline{1.3617270}$ 2.6269560 so is 423.6 so is 1.35 0.1303338 3.1890108 1.4920608 to the 4th term 42547—1.6288650 4th term 1.2621  $\overline{1}.1011257$  Instead of subtracting the Logarithm of the first term, the withmetical complement of it may be added; and the sum, after subtracting 10 from the index, is the Logarithm of the fourth term.

Arithmetical Complement of any Logarithm is found by subtracting it
from 10.—Hence the 16th and 17th examples will stand.

As 36.32 Arith Comp. 8.4398542 | As 2.46 Arith. Comp. 10.6090649 is to 3.648 Log. of is 0.5620548 is to 0.52 Log. of is 1.3617270 so is 423.6 \_\_\_\_\_\_ 2.6269560 so is 1.25 \_\_\_\_\_ 0.1303338 to the 4th term 42.547—1.6288650 4th term - - 0.1011257

The easiest method of finding the arithmetical complement is to begin at the left hand, and subtract each figure from 9, except the last significant figure upon the right, which must be subtracted from 10; but when the index is negative, add it to 9, and subtract the rest as before.

#### IV. INVOLUTION.

Multiply the Logarithm of the given number by the index of the power to be raised, and the product is the Logarithm of the power required.

If the index of the Logarithm of the given number happens to be negative, the product will be also negative; but the number carried from the Logarithm decimal to the index is positive, so that the difference will be the index of the Logarithm product, and to be set down with the sign of the greater.

.00000000000000000000000000000000000000	000000000000000000000000000000000000000
0184884 the power required.	}

In the 20th example, after multiplying the Logarithmic Decimal by 4, there is one to carry to the index; but the index being here negative, the difference of the number carried, which is positive, and the product of Logarithmic index, and index of the power, is set down for the Logarithmic index of the power sought, with the sign minus, which is the sign of the greater.

In such cases as example 21st, in which it is necessary to put down the whole operation of multiplication, the figures of this product which are cut off to the right hand are the same number of Decimals as in the Logarithm, and the figure or figures upon the left of the point, are those which are to be carried to the index, and managed as shown above.

### EVOLUTION.

Divide the Logarithm of the power by the index of the root, and the quotient will be the Logarithm required.

Ex. 22.—Find the square root of 688.0129. 688.0129 Log. of is 2.8375966 which divided by 2, the index of the power, the 1.4187983 quotient is and the number corresponding to and the number answering is .123, this is 26.23, the root required. the root sought.

Ex. 23.—Find the cube root of .001860867. .001860867 Log. of is 3.2697153 which divided by 3, the index of the power, the 1.0899051 quotient is

When the index happens to be negative, and the index of the Logarithm of the given number cannot be exactly divided by it, add one or more to the Logarithmic index, by which an exact quotient may be formed, and carry the same number as ten to the decimal places when dividing the rest, and the quotient is the Logarithm of the

000000000000000000184884, the Log. of which is 47.2668992 to the index of which add 1, and divide by 16, the quotient is  $\bar{3}.0791812$ the number answering to this is

root: as,

Ex. 24.—Find the 16th root of .0012, which is the root required.

In this example, by adding 1 to the index, the first figure of the quotient is  $\overline{3}$ , and carrying the 1 as 10 to the decimal the other part of the quotient becomes .0791812 as above.

## LANDSURVEYING.

- 1. THE chief purposes of Measuring Land is to find the Superficial Content, or Area, of any given extent, as comprising a portion of the Surface of the Earth, and to delineate a plan of its figure upon the same plane \*.
- 2. The means usually employed for taking the dimensions of Land, is either by using the measuring chain only, or by using the chain with an angular instrument. The first of these methods of which we are immediately to treat, is the application of Practical Geometry, and the second is that of Trigonometry.

#### OF MEASURING A STRAIGHT LINE.

3. To find the true distance between two given points, upon the surface of the earth is yet a desideratum in the art of measuring, as the best measurements of this kind which have been made, are allowed only to be approximations to the truth; but as the difference

THE plane of the horizon is here to be understood; as this, and the Spherical Surface have almost no sensible difference upon the extent of the largest Estate.

in some cases have been so very small, that in regard to all practical uses, and even for the establishment of theory, these justly may be considered perfect. As an instance of this, the base line used in the survey of the meridional arc of England begun in 1784, was at that time measured with glass rods, and after the corrections for variation of temperature, &c. was found to be 27404.01 feet in length; and in 1791, the same line was again measured with a Steel Chain made by Ramsden, was found after making the same corrections, to be 27404.32 feet; the difference of these measurements being only 2.82 inches in 5.228 English miles. However, in the practice of Landsurveying, such accuracy seems never to have been made in any case whatever, whether the obstacles to this may have arisen from the want either of science in the practitioners, or the use of proper instruments.

4. As the chain is the instrument used for directly measuring distances between given objects; it is always necessary to compare it before using with a true standard of feet, a measure which should be provided from a respectable instrument maker. A good method of ascertaining the length of the chain, or rather the difference it may have from the statute length, which we shall here denominate the chain error, is first with the standard to mark out the statute length upon the base of some building, pavement, or other immoveable place whereupon the chain can be fairly stretched; so that if there be any difference, this will appear plus or minus of the Statute length. After this verification of the chain, it may then be carried to any other place, but before commencing the intended measurements, mark there also its length upon another fixed place, to which during

the survey it can be at any time applied, and by this means any va-

- 5. The chain commonly used in taking the dispensions of land, consists of one hundred links, each of which is joined to the next by three rings that are always included in the length of every link, and the whole is made of iron wire, excepting the brass counters hung at every tenth. Besides the chain, a rod called an offset-staff, equal in length to ten links, and divided accordingly, is used for measuring short distances. The length of the English statute chain is 66 feet, and the Scots chain is 74% feet, so that each link of the English chain contains 7.92 inches, and the same of the Scots chain 8.88 inches.
- 6. The distance which is to be measured should be marked out with picquet staffs or poles, at least one at each extremity, and such extreme points are called stations. The operation of measuring any line whatever, requires at least two persons employed, the one to lead the chain, and the other to direct it. The first or leader, is provided with ten pins or arrows, and lays his end of the chain by the direction of the follower in a straight line with the distant station, while the latter holds the other end precisely at the other station. At the end or every chain laid between the stations, the leader sticks an arrow into the ground, at which the follower finds always a precise point to hold his end for the next length, and they proceed in this manner till the whole line is measured, while the follower successively gathers as many arrows as there have been chains laid out upon the distance.
- 7. All surveys made with the chain only, supposes the ground nearly smooth and level, and if otherwise the conclusions derived therefrom

cannot be correct; who any line having an inclination to the plane of the horizon must be longer than if measured upon it, as such becomes the hypothenuse of a right angled triangle, the difference of level of its extremities the perpendicular, and the horizontal distance the base; therefore, the finding of distances, measured upon sloping and undulated grounds, belongs to the use of angular or levelling instruments, and requires the application of Trigonometry.

#### OF PRACTICAL GEOMETRY

UPON THE GROUND WITH THE CHAIN ONLY.

8. To find a point d nithout a given line A B, so that the line A d shall be perpendicular to A B.

SET a staff at any convenient point C, and about half the distance which d is required from AB: then with the length CA set another at b, and make C d in the same line and equal to C b, and d is the point required; that is, A d will be perpendicular to A B.

- 9. To make a line CD parallel at any given distance to another line AB. AT c and d, any two points taken at pleasure upon AB, make c b and d c both perpendicular to AB (8.): then mark off c C and d D, each equal to the given distance, and the line CD will be parallel to the line AB.
  - 10. To find the distances between two stations A and B, without measuring between them.

MAKE C D, at any convenient distance, parallel to A B (9.), and A C and B D both perpendicular to A B (8.); then measure from C to D, between which is the same distance as from A to B.—This

a hedge or other fence whereupon it may be impracticable to measure directly, wherefore the line C.D is made on ground free of obstacles equal to A B on which its length can be easily taken.

### 11. To continue the line A B to any given distance B E.

At any convenient short distance make C D parallel to A B (9.): set a staff F in the same line with C D, and at the given distance B E: then make F E perpendicular to F D C, and equal to C A or D B, and the point E will be upon the line of A B produced.—This example is applicable to all fences or fronts of buildings, the uniformity of which is broken with trees, projections, or other impediments, and that intercept the eye from directly forming a continued straight line.

# 12. To find a point C which shall be on a straight line between A and B, by standing between these objects.

LET a person with a rod C D lay it from any point C, and first point it to B; next, keeping the end D fixed, let him turn the other towards A; again, keep C fixed, and bring D pointing to B, and so on, pointing the rod alternately upon A and B, until it point upon both these objects at the same time, and C will lie in the line A B.

Otherwise (better by two persons, C and D).

LET C and D each hold a staff any where at pleasure, between the objects A and B, and first let C put D in a straight line with B; next D, keeping stationary, moves C into a straight line with A: again, C stationary, directs D upon B, and so on alternately, till they both settle upon the straight line A B.—The use of this example is always necessary in the case of rising ground lying between A and B, which

may cover each from the view of the other, as either of these operations may be performed upon a place from which both are seen.

# 13. To let fall a perpendicular upon the right line A B, from an inaccessible object D.

Upon the plane mark out the line AB, and make FB perpendicular to AD, and AH perpendicular to BD: then through C the intersection of AH and BF, continue the line DC, by fixing a staff in E on AB, and ED is perpendicular to AB.

#### Otherwise.

MAKE A a and B b perpendicular to A B, of any convenient length, but equal to each other, and on A b measure the lengths of a c and d b; then, by proportion, a c+d b: a c:: A B: A E

or, 
$$\frac{a c \times A B}{a c + d b} = A E$$
Also,  $a c + d b : d b :: A B : E B$ 
or,  $a c + d b = E B$ 

Hence, by measuring out the length of A E or E B, either will determine the point E.

# 14. To find the distance of an inaccessible object D, from any given point A.

THROUGH A form the line AB, upon which let fall the perpendicular DE (14.), and measure on DE any convenient distance EG; next make CGF parallel to AB, and measure the length of CF: then, by proportion (Theor. 16.),  $\frac{1}{2}\overline{AB-CF}:GE::\frac{1}{2}\overline{AE+EB}:DE$ 

or 
$$\frac{G E_{\times}A E + E B}{A B - C F} = \frac{D E}{.2}$$

#### Otherwise.

From the point A mark off AB of any convenient length perpendicular to AD; also BC of any length perpendicular to AB, and find a point E in the line of CD upon AB; then by measuring the respective lengths of AE, EB, and BC, we have by proportion, BE: BC:: AE: AD; or  $\frac{BC \times AE}{BE} = AD$ .

15. To find the distance between two inaccessible objects, A and B.

FORM upon the plane the line C D, as nearly parallel as it can be made to A B, and let fall the perpendicular A a and B b upon the line C D (14.); also find the lengths of A a and B b (15.), and measure the distance ab; then we have A  $B^2 = Bb - Aa^2 + ab^2$  (Theor. 10.), or A  $B = \sqrt{Bb - Aa^2 + ab^2}$ .

16. Through any given point C to form a line parallel to another given inaccessible line A B.

FIRST mark a point D at pleasure, and find another point E in the line A D, which shall be on the continued line of C B; next make E G parallel to B D, and G C F parallel A D, meeting B D in F: set a staff at H, on the mutual intersection of the lines E G and A F: then the line formed through H and C, as I H C K, will be parallel to A B.

### OF MEASURING LANDS WITH THE CHAIN ONLY,

### AND FLANNING THEREFROM.

- 17. IN lands that are bounded by straight lines which are formed by hedgerows, trees, and drains, the practise is under such circumstances to measure the respective lengths of the sides by some of the preceding methods (10, &c.); but where these are free of obstacles, each part may be measured directly upon itself.
- 18. The Planning or Protracting of Figures from actual measurement requires the use of several drawing instruments, as compasses, drawing pen, parallel rulers and scales, each of which we shall describe severally, without supposing the use which may have been already made of these in the Practical Geometry.

The compasses, (Fig. A.) are usually made of silver or brass, having the joints and points of steels, the joint at the top is a steel axle, upon which both the legs turn, and is provided with a turn-screw for lessening or increasing the friction of this part. The motion of the legs upon the axle should be uniform and smooth, so as to keep steadily any position given to them, without springing or starting back, and the whole well polished, which makes them be easily kept clean. The point of one of the legs is transmoveable, in the place of which can be substituted, singly, two other parts, called pencil and ink legs, 'the first of which is used occasionally for describing or drawing circles and arcs in lead, and the other the same in ink. When the compasses have both the legs fixed they are called dividers.

The hair compasses, Fig. B, have a movement at the screw in the middle of one of the legs, by which the point of it after being put near to any distance, can be brought either backward or forward exactly upon the line of division.

The drawing pen, Fig. C, is for drawing times in ink. The ink is put between two bent steel blades, which by the screw b can be made nearly to meet at the points; so that the ink is let out less or more during the time of drawing, according to the required strength of the line. The ink point of the compasses is constructed in the same manner. The head of the drawing pen is usually made to screw out with a steel point affixed to it, which is used for pricking or tracing off the first protraction upon clean paper.

The parallel ruler is for drawing mechanically parallel lines at any given distance from each other, by one of the blades moving parallel to the other while this is kept fixed. The best movement of this kind is the moving blade to go out perpendicular to the resting one, as Fig. D; but this instrument is as often constructed to have its movement obliquely, as Fig. E. A surveyor should be provided with three of these, the longest two feet in length, the next one foot, and the other six inches, and the two first are better if made of brass, and the last of ivory. As this instrument is of constant use to the draftsman and surveyor, it is of the utmost importance to verify it, which may be done in the following manner: first open the blades at any convenient distance, and lay the instrument in this position upon the paper, and along each blade draw a straight line, as A B and DC; next reverse the instrument by laying the edge by which A B was drawn, upon DC, and bring the other upon A or B, for instance upon B; then, keeping the first steady upon'D C, draw a line through B, which, if the ruler is just, will coincide with AB, but if otherwise, will be Ba

cr Ba, and the angle a BA or ABa will be double the angle of the error which the blades make with each other: for let Db be parallel to AB, and the angle CDb be the error of the instrument from parallelism; now if it be reversed, and the edge put upon Db instead as above upon DC, the other will describe Bb, making the angle ABb, equal to the angle CDb, for DB and AB are parallel: but again, as first, make the edge coincide with DC instead of Db, and draw by the other edge the line Ba, then b'Ba must be equal also to CDb, for DC and b'B are parallel, and consequently equal to ABb': hence the angle ABa is equal to twice the angle CBb.

The T square, used by architects, makes very good parallels, if made to slide along the smooth edge of a drawing board, or a straightedge laid and kept steady upon the paper. Sometimes these squares are provided with a revolving head besides the square one, which can be fixed stationary by a screw through it, to any given angle with the blade, by which, lines oblique to the side of the board may be drawn through any given point.

The scales are usually made of brass or ivory, but better if of brass, as this metal bears the pressure and point of the compasses without injuring the divisions so much as those of ivory, especially the diagonal scales, which are used only by applying the compasses upon them. This instrument, Fig. E, contains so many primary or large divisions, as 1, 2, 3, 4, 5, &c. each of which may represent the distance of one mile, one chain, one hundred feet, or any other measure fixed upon previous to using. One or both of the extreme divisions of these is divided into ten equal parts, by diagonal lines drawn parallel to each other, but crossing obliquely eleven other parallel lines, which forms the breadth of the scale, and also divides it into ten equal parts. It will appear, that by this mode of division and position of the parallel

lines, the 100th part of one of the primary segments may be obtained; for first beginning at 0, and looking up the perpendicular line of division the intercepted parts between it and the first diagonal 0 1 are gradually lengthened, till the last or uppermost which is equal to one tent's of the primary segment; so that hy this construction, the perpendicular is equal to 10, the first subdivision is equal 1, the first division upon the perpendicular is equal 1, and call the least intercepted part between the perpendicular and first diagonal a, we then have by proportion (Theor 16.), 10:1::1:a, or  $a=\frac{1}{10}$  of the subdivision; and every subdivision being the tenth part of the primary segment, consequently a is equal 100th part of the same segment.

In planning grounds which have been measured with an hundred linked chain, the above division of the primary segment is used, as each of these represents 100 links, or one chain length, and the diagonal shows all the intermediate numbers of links from 1 to 100. As an example, let the length of 232 be required from the scale; then we have first two primary segments equal to 200, and three subdivisions equal to 30, now if we add the second intercepted part from the bottom, we have collectively three parts equal to 232; but which in whole can be found on the second line from the bottom, being intercepted between the third diagonal and perpendicular 2. The same may be shown of any other number; for the digit part of the number is always intercepted between a diagonal and the perpendicular, upon the parallel line of the same name from the bottom.

Besides the above application of the diagonal division of the scale in representing the parts of 100 links, it is equally applicable to any other measure whatever: for instance, let the above primary segment be subdivided only into eight equal parts instead of ten, then by the same proportion we have the eightieth part of the same division, so

that this scale will have to miles, furlongs, and chains. The same may be shown in feet, inches, and tenth parts of an inch; for if the primary division is divided into 12 parts, and the height of the diagonal as before into 10, we have the first representing feet, the second inches, and the wird tenth parts of an inch.

19. As the form **at a crooked** line cannot be derived from measuring lineally the required part only, excepting this be a portion of a known curve or circle, it hence becomes always necessary to refer the measure of such lines to a common standard, upon which the forms of these will appear. The most convenient measure for this purpose, is a straight line made near and to lie opposite the crooked line; for let it be required to find the form of the line A b c d E: with two or more poles mark out the straight line F K, opposite and conveniently near to A b c d E, and measure alternately the greatest and least distances between them, as the perpendiculars AF, bg, ch, di, EK; also measure the parts F g, g h, h i, i K, which together will be the necessary dimensions for constructing the crooked line A b c d e E; as draw first the line F K, and mark out the distances respectively of the points F, g, h, i, K; next set off the perpendiculars A F, b g, c h, d i, and E K, according to the measurement of each, and join their extremities A, b, c, d, E, which will be the form of the line required. In curved lines, it is obvious, the nearer the perpendiculars are to each other, the form of the curve will be the more correctly described.

The line F K is called a station line, and all the perpendicular measured to the boundary, from it, are termed offsets.

20. When crooked or curved lines recede so far from the station line E L, that the offsets are inconveniently lengthened for measure-

ment, as of the part CD opposite to GL, it is better, in this case, to mark out another line GK, joining and making an angle with EG, but nearer to GD than GL, by which the continuation of EG.

21. The relative position of two lines **E G**, **G** K, forming any angle with each other, is found by measuring the subtense \* of the angle **E** G K or K G L; for mark off the equal distances G h, G k, and measure the subtending line h k between them, the lines G k, G h, h k are the dimensions of a small iscoles triangle G h k upon the required angle.

Protraction. Draw E L, and mark off the distances E G=360 and G k=100; upon G k as a base, describe with G k=100 and h k=150 the triangle G h k, and produce G h as far as. K, then E G and G k are in true position to each other. When the angle E G K is very obtuse, it is better to take the measure of the subtense h k of the angle K G L, as the point h can be more accurately determined, because the intersection of the sides G h and h k are not so oblique as in the other.

In making the actual measurements of land, an instrument called a cross staff is sometimes used, for marking out with greater expedition the offset lines perpendicular to the station line, than could be done by geometrical construction. This instrument is constructed with four sights, fixed at right angles upon the head of a staff of convenient length, which is shod with iron for sticking into the ground. It is applied by being placed upon the chain or station line with two

<sup>\*</sup> The subtense is a line joining the two sides which form the angle at equal distances from the angular point.

of the sights in that direction, and by looking through the other two, a mark on a perpendicular line to the chain is thus found upon the boundary, where the class is to be measured; or it is moved backward or forward upon the station line till the perpendicular formed by the intersecting sights falls upon any given point: but as this instrument is not provided with any adjustment for making its plane parallel to the horizon, its operations should always be limited to very short distances; therefore practical surveyors prefer as equally accurate, to keep their station lines as close to the boundaries as can be done, which makes the offsets only be a few links in length, and are taken perpendicular, by the eye first laying the offset rod as nearly perpendicular across the chain upon the station line, and then measuring with it forward to the boundary in that direction. By this method, or using the cross staff, the station line is usually measured, and the offsets upon it are taken at the same time.

22. The operation of measuring a line with offsets as E K, is performed first by measuring with the offset staff the offset A F=15 links, next stretch the chain from the station F towards the station K as described in (Art. 6.), and proceed measuring till some part of the chain lie opposite the point b upon the boundary to which the next offset is required; then find the point g upon the chain by (Art. 21.), so that b g will be perpendicular to F K, and measure b g=25 links; also note the number 120 the distance in links found by the chain, between F and g. In the same manner continue till the chain lie also opposite c and d, where likewise as above measure the offsets c h=17 links, and the distance of h from F is found 230 links, and the offset d i=30 links, and i distant from F is 360 links. Lastly, the whole distance F K is found to be 513 links, and the offset K E at the sta-

tion K is equal 10 links, which measurements together make the discretion mensions of the boundary A b c d K.

As the measurement of the line F K represents a straight line, it is necessary that this be actually measured as such; for if those employed have deviated to the right or left of it, this measurement will not only be lengthened, but likewise all the effects from it be measured long or short of the true dimension according as the deviation approaches to, or recedes from the boundary; therefore the persons who direct and lead the chain, should be well instructed and practised, till able to keep it at every point in a right line between the picquet staffs, which mark out the course under measurement.

In the case where the ground upon which offsets are required is sloping or rising from the station line to the boundary, it is better to measure these from the highest extremity to the lowest, by first putting the one end of the rod upon the surface, and keeping it as nearly level by the eye as possible, and from the other suspend a plummet or drop a small stone, which will mark the horizontal distance of the rod upon the sloping surface, and also a point from which to measure the succeeding length, In the same manner continue till the whole length of the offset is measured, which will be sufficiently near to the true horizontal distance.

It is better, as on the figure, to write the distance upon the station line where the offsets are taken, in links, as Fg=120, Fh=230, Fi=300, &c. instead of noting the chains and links separately. In the event of a station line exceeding ten chains in length, it is necessary at the end of the tenth, or 1000 links, that the whole arrows which have been now taken up by the follower be again returned to the leader, who sticks the first at the end of the eleventh chain, and both proceed as before; but in the act of returning the arrows, the follower

marks the place of the tenth arrow till the eleventh is stretched, and the leader sticks in the eleventh arrow; or otherwise if the eleventh chain is stretched before changing, the leader marks the place of the and of the eleventh till the follower brings up the arrows, who sticks one at this point, and gives the remaining nine to the leader. ever, instead of marking the places of the tenth arrow or the end of the eleventh chain, the writer of this uses an eleventh arrow, but which has a peculiar mark from the other, as half the length, &c. which the leader always reserves to be put in at the end of the eleventh chain length, so that when the leader at this point receives the arrows, he lifts it again and sticks one of the ten in its place, and again carries it in reserve for the same purpose at the next change, by which means are avoided the accidents of losing the point, which may happen from not marking the place of the arrow sufficiently, and afterwards while changing not keeping the spot in view. It is obvious, at the end of whatever number of chains measured by this method, that this eleventh arrow is not taken into the enumeration: but has been held merely as a mark during the changes made on the whole line.

In measuring with the chain, the assistants should be very careful to give out its full length, by keeping the handle within two or three inches of the point of the arrow, and holding this perpendicular while sticking it into the ground, which is easily done by the leader putting all the fingers of the right hand through the handle, and the arrow on the outside between the handle and thumb. On the other hand, the follower should hold the chain precisely at the arrow of his end, until he finds the leader has put another in a direct line with the stations.

23. If the sides of a field which is to be measured is found to assume

But if the boundary of the field consist of crooked fences, and forming a figure nearest also to the triangle, as E F G, plant the stations e, f, g, under the same circumstances as shown above for a, b, c, and measure the station lines ef, fg, and ge, with the necessary offsets upon each as shown in the figure, and exemplified in (Art. 22.) which is at every turning and recess of the boundary from the station lines.

Protraction of the triangular field having straight sides. First construct the triangle a b c (Prob. 1.), for example as in the figure from a diagonal scale of one half inch to the chain or 100 links, making the side a b=420, b c=345, and c a=475; next set off perpendicular to a b the offsets a a'=10 and b b'=20, and draw indefinitely the line a' b'. In the same manner mark out the offsets b b''=17, c c'=25, c c''=12, and a a''=14, drawing the straight lines b'' c' and c'' a'' intersecting each other and a' b' in the points A, B, C, and the figure A B C is the true boundary of the field measured.

Protraction of the triangular field having crooked sides. As above construct the triangle efg, making the side ef=420, fg=345, and ge=475; next mark off upon the station line ef the offset ee'=12, and the distances 80, 130, 230, 330, and 400 from the station e upon

which were treasured respectively from them, as 15 at 80, 80 at 130, 8 at 250, 26 at 330, 15 at 400, and 15 at the station f; in the same manner preced to make out the intermediate distances, at which offsets were taken upon the other station lines fg and ge, and at the same time as above constructing the offsets perpendicular to the respective station lines of each; after which join the extremities of all the offsets, and thereby forming the crooked lines EF, FG, and GE being together the boundary of the field, which will be correctly delineated.

24. As another example of surveying a crooked sided field, for it is such that oftenest occur in practice, let the field ABCD, by placing the stations a, b, c, d, be resolved into a polygon of four unequal sides, as the most convenient figure for taking the dimensions upon its boundary. The surveyor in this case may either place all the stations before measuring, or place and measure them in succession. After all the station lines and the necessary offsets upon each are measured, it is requisite that both the diagonals a c and b d be also taken, by which the polygon is divided into two triangles, being either a b c and a c d, or a b d and b d c.

Protraction. First draw ac or bd, but in this example let ac be drawn, and upon it as a base construct the triangle abc and acd, according to the measured lengths of the respective sides of each, as marked upon the figure. As in (Art. 23.) set off the offsets upon the sides of the polygon abcd, and the extremities of these will mark as before the boundaries of the field.

In this example a good proof of the accuracy of the measurements of the station lines are afforded from the measurement of the diagonal bd; for if the length of bd be measured by the scale from which the

with its measured distance, and which is an instance that shows necessity of providing similar proofs for the salesurement of every and gure whatever, whereby the results to be detailed from them may be safely relied upon.

25. FIELDS which have more than four sides commonly require as many station lines as each has sides, as A B, BC, C D, D E, and E A, which are measured after the same manner as the described in the fields of three and four sides, but this field will require two diagonals to be measured between the opposite angles, as B D and B E, or C E and A D, for protracting it; for by the figure there are three triangles to be made, as C D B, D B E and A B E, the two first of which can be constructed upon the base B D, but the other requires the other diagonal B E for its base.—It farther may be made evident, that every figure having more than three sides, requires as many diagonals measured between the opposite angle as the figure has sides more than three; for let other two sides be formed, as E F and F A, which will increase the same figure to six sides, as A B, B C, C D, D E, E F, F A, and then a third diagonal A E will be necessary for a base, upon which to construct the triangle A F E.

It is upon the above principles that the most accurate measurements of land are made with the chain only, that is first by circumscribing or inscribing the boundary with station lines, and forming diagonals between the opposite angles by which the figure assumed by the station lines is divided into triangles. However, as the most careful measurements are not perfect, nor each have always the same ratio to its true distance, a choice of position to each other and the proportions of the sides is necessary to be considered,

so as to constituet a series of triangles to have the same accuracy with which they may have been measured. As an instance of this practical remark, for it is in tractice alone it is admissible and by which it is discovered; let a series of triangles be formed, such as whose sides have great differences with each other, and in this case the intersection of the sides at one of the angles will cut extremely oblique, of which the true point of intersection cannot be determined: but on the contrary if the sides of all the triangles have small differences with each other, the intersection will the angles will be nearly the most direct possible, and upon each the point of intersection will be definitely marked.—Hence the nearer equilateral are the triangles, and equivalent to each other, the measurements which have been made of them can be the most accurately protracted.

- 26. The measurements of every polygonal or many sided figure may be verified by diagonals measured to every second opposite angle from each of these alternately; for let the polygonal field ABC DEFGH be constructed from the measurements of the triangles BCD, ABD, ADH, HDF, HEF and HFG, and besides these let the diagonals AC, AE and EG have been also measured between every second opposite angle and from each alternately: it appears that AC is a base to both the triangles ABC and ACD, and AE is a base for the triangles ADE and AHE, and also EG is a base for the triangles EHG and EFG, by which each of the quadrilateral figure BCDA, ADEH, and HEFG are verified by its respective diagonal (Art. 24).
- 27. Where deep recesses or great bends are in the fences, as at E, to which the distances are too great to measure with the off-

set staff from the station line A B, construct triangle within the recess upon a base from two known points of the station to C D E, upon which from two of its sides of C E and E D, correct offsets can be taken to the boundary.

If a recess consists of two straight sides as  $\bullet F$ , F b, mark the number intersected by the continuation of them and the station line, as 326 and 410, also marking other two convenient points upon it, as 340 and 400 and measure the distances 116 and 108 from each to F as on the figure, whereby F is constituted that apex of a small triangle, having the difference of 340 and 400 to its base which is a part of the station line  $\Lambda$  B?

Instead of a triangle being formed upon the station line for measuring the boundary of a recess, a trapezium or any other polygon may sometimes be more suitable for this purpose, as HIKL, and by measuring the diagonal IL or HK, as in (Art. 24.), is divided into two triangles, being either HIK and HKL, or HIL and LIK. In the same manner as shown in (Art. 25.) the boundary of any recess whatever may be inscribed or circumscribed by station lines forming a polygon of any number of sides, but one of which must be always a known part of the station line AB.

In the case of a pond of water or other obstacle by which it is impracticable to measure the diagonal MP or NO in the polygon inscribing the recess, it is necessary in this example to measure the subtense of the angles LMO, MNP, MOP, and OPN, as in (Art. 21.), by which the angular position of the lines MO, NP, and OP will be known.

Let it here be observed, of this method for finding the angular positions of the sides of a polygon by measuring the subtense at short distances from the angular point, should only be applied to such cases as

do not proved two or three chains; for a ected when the subtense will make a considerable true distriction at the extremity of a long line. I the line of many respectable measurers of land, and even give it an ignorant preferente to the use of angular instruments; but as a better proof than the number of practitioners, the angle M N P be taken by measuring the saltense N P, the true length of which is 150 links at the distente of 100 links from the angular point N, and suppose N P and N M equal, and each links, then by (Theor. 16.) we have 100: 150 :: 1000 : M P=1506, the true length of M P: now let an error of one link take place in the measurement of the subtense, that is, instead of being measured the true distance 150 let this be only 149; then we have by the same proportion 100:149::1000: MP=1490. which is 10 links short of the true length of M P: again let the subtense be measured 151 instead of 150, then as above 100: 151:: 1000: MP=1510, which is 10 links too long. Hence in the same proportion will the error be multiplied as the line is longer than at the point where the subtense was measured.

When the angular position of a fence QR is required upon the boundary, mark its intersection S upon the station line by placing a pole upon the chain in a line with QR, and also mark another point T; then measure with the offset staff the distances SQ and TQ, which will constitute the triangle SQT, having its base ST a known portion of the station line and one of its sides SQ in the same line of QR.

**Protraction.** First mark out the distance s = 476 and  $s' \Gamma = 565$ , and with the sides 35 and 42 construct the triangle as upon the figure: then produce S Q beyond the boundary to R, and Q R is in true angular position to the boundary q r.

Where buildings or other angeles to the boundary, as a house G, many the dimension of the station line as at 520 and 605 the beasure to the point from the same intersections as 50 and D. If the direction of the building be required, measure its least of and breadth 32, and at the same time noting the meeting of the property or other lines upon it, as represented on the figure by 20 and 30 cm measured from the appropriate point to the lines marked fence.

Protraction. First lay off from the state. A the distance 520 and 606, and from these points, with the distance 0 and 70 as sides, construct as in the figure a triangle, the aper of which or angular point opposite the station line is upon the corner of the building to which these distances were measured.—Next produce the sides 50 and 70, and lay off upon the continuation of 50 the length 64, and upon the continuation of 70 the breadth 32; then draw the opposite sides parallel, and the building G is delineated both in position and magnitude.

If the position of a rectangular building W, lying nearly parallel to the station line be required, first mark the points of intersection by producing its opposite sides u u' and v v' upon the chain as U and V; then measure the distances U u and V v, and its breadth u u' or v v' and length u v.

Protraction. From the station a lay off the distance of a U= 343 and a V=403; next from the point U with the distance 55 describe an arc u'' u u''', and from the point V describe another arc v'' v v'', and draw u v touching both the arcs: then draw the lines U u u' and V v v' both perpendicular to u v, and make u u' or v v' each equal the breadth 34 and draw u' v', which will delineate the building W.—It is to be noticed by the construction of the above, the building is sup
derectangular, by which the length will be found 58 as measured.

When it has been also better line A. B is intercepted by a small piece of a small but cannot be measured, measure as far as c and set out the production of the may have any convenient distance, also beyond the impediment X, so that a may be made produced, also beyond the impediment X, so that a may be made produced, also beyond the impediment X, so that a may be made produced, also beyond the impediment X, so that a may be made produced to f on the line A. B.—Now if e f, when f is found upon the line of A. B, be equal to d c and the angle e the a right angle, the distance across the obstacle X is equal to the produced distance of d c. Hence by measuring f B the whole length of A B is equal to A C+d e+f b.

It occasionally is necessary to cross or pass through a fence C D with the station line A B as at a, b. If this fence be a hedge, in most cases the chain may be passed between the stems of it upon the line A B, having the chain stretched as in open ground; but if it be a wall of stone, turf, &c. through which the chain cannot be passed, first measure to the side at a as 278, next with the offset staff laid horizontally across the wall in the line of AB, and with its end adjusted by a plummet exactly over a, find the number of links as 6 upon the rod by again suspending the plummet above b, which add to 278 making together a distance 284 from A to b; then, subtract this from 300 and the remainder is 16, which difference lay off with the chain from b towards B, and this will mark the place of the third arrow from A to B, beyond the wall.

28. After having described the methods of measuring the station lines with offsets upon them, the joining with diagonals the opposite angles formed by the station lines inscribing or circumscribing a shigle field, and also the various figures of the boundary and objects connected

ples by another more general, showing the more of measure delineation of several fields adjoining each

was begun by first fixing the station a, so that we extremities A and B of the boundary A B were both seen from a, we next fixed b in such a manner as the line a b could be measured free of obstacles by crossing the rivulet; after having b fixed we went to the meeting of the river and the boundary at E, and placed the station pole at C, by which the line b c could be measured without a part of it falling into the river, and also free of interruption apon the banks. The part of the boundary E F being a straight line, it was only necessary to place the station a at a convenient distance from it, and to be seen from a and a and some part of the line a a as at a. Proceeding as far as the corner a, we found that a would be seen on a straight line from a point a, and into the road at a, and also that part of the station line a a, which is intercepted in the same inclosure; therefore both a and a were constituted stations.

The stations a, b, c, d, e, f being now posited, we went along the road till nearly opposite B, where we fixed the station g, to which a straight line could be measured from a, and likewise another to some part about h opposite C. Proceeding till opposite the bend C, the station h was placed so that both the straight lines gh and ah could be easily measured, and also another hi towards the river, where i was made another station, from which the distances of hi and li could likewise be taken.

Having now either circumscribed or inscribed the whole boundary ABCDEFG, by marking out the station lines ag, gh, hi, ib, be, cd, de, ef, and fa, and likewise ab skirting the rivulet, we con-

wanted out upon the ground, and has have at expressed upon the plan, and which were necessary for the station lines into triangles: besides e = 1012, e' = 1046, e = 878, While waring along a b, we marked \* the point a' as which takes the form of the curved fence opposite this line (Art. 19% and also noticed the intersection of this fence with the chain. The introduction of the continuation of the straight fence from the boundary at O and c' and c' and c' and c' and c' and c'. The extremity of the straight fence F h' was made the apex of the triangle 8'9'h', and likewise the intersection upon ab if continued. suring the lines de, e f and zh, the points of the intersecting fences were all observed upon the chair. The angular position of the fence l' k'. upon the opposite side of the river to the station line ib, was found by marking out the triangle i'm'n' from it, having one of its sides i'm'. on the same line of ik. The methods of taking the measurements of the other parts as expressed upon the figure, have already been sufficiently described in the preceding articles.

Protraction.—The protractions of all surveys are commonly drawn first with a black lead pencil, and afterwards the boundaries and other objects of the lands are drawn with the drawing pen in India ink: but if it is required to preserve the station lines upon the protraction, these gone over with a tracing point, will impress the lead into the paper, so as to leave them afterwards always visible.

<sup>\*</sup> The station points and all others upon the station lines, to which other lines are to be joined, should be marked with small pegs stuck into the hole in the ground made by the pole, by which these points may readily be found afterwards, at least till the survey is completed:

from any scale, as in the plate of half at severy 100 lines, upon this as a base, with the sides a catalog construct the same a be; next making a c another base, construct appearing upon it the triangle a fe, upon e b the triangle e b d, and upon the triangle b c d.

Again, upon a b as a base, construct the triangle a h b, also upon a h make the triangle a g h, and upon b a sonstruct the triangle b i h, which will conjoin together the series of triangles a b c, a f h b e d, b c d, a g h, a g b, b i h.

From a upon a b, mark the points a', b', g', according to their respective measured distances from a, and from a'e; now, by applying the length of the proof lines from the scale, c'g=1012, c'i=1046, c'e=878, a'f=804, and a'e, the degree of coincidence of each will show that of the accuracy with which the survey and the protraction has been made of the station lines, (Art. 24.)

Supposing that each proof line answers to its measured distance upon being applied from the scale; next construct the small or lateral triangles b' d' e', b' e' c', f' g' h', i' m' n', and mark off upon the station lines the respective offsets, and through the extremities of these draw the corresponding boundaries (Art. 19.); also join the points between the station lines where such are intersected by fences, as, join the straight fences c c' and F h', which will finish the delineation of the whole of the measurements of these five fields.

In all surveys to be made with the chain only, the lands should be divided by the station lines into the smallest number of triangles, consistent with its general figure: but these should be so disposed to kirt very near the boundaries, by which the windings and other deviations from a right line will be easiest measured by the preceding methods, and also to have the fewest diagonals necessary either for

water the besidery measured by a great matabet of station lines, this will be be believed by a great matabet of station lines, this will be be be better and proof lines, and the whole protraction much shape intricate, and bertainly less accurate, than by lawing to unite lines in protraction.

After an applying the proof lines to a protracted series of triangles

the measured distance, the first thing to be done in this case is to revise the protraction, in the measurements of the proof lines, then the diagonals by which the measurements of the proof lines, then the diagonals by which the measurements of which the error must necessarily appear.

It is the practice of some surveyors, who pretend to great accuracy, to have a great many proof lines made almost in every position, which by them is termed tying the survey; but such labour is unnecessary, and will rather be the cause of inaccuracy than a proof; for after diagonals are measured as single proof lines in the best positions, (Art 25.) all others which are out of this position must be an inferior proof of the accuracy of the survey, because in the practice of measuring every line, it is impossible to form, even with the greatest care, that coincidence which is so evidently demonstrated to take place in theory; therefore an extraordinary number of injudiciously disposed proof lines, can only at the most shew some singular agreement of errors, if taken place upon those of the best position.

29. The best manner of forming a series of triangles for surveying an estate, or other considerable extent of land with the chain only, is first to mark out to the best advantage, that is upon the clearest and most level parts, two or more straight lines quite through the

the distance from each other of three forms. Then the length of the which the triangles are required. Then the land, the length of the triangles A c b, A b a, a b f, B f D, a D B, and d, C d b, d b a, b c c, c e F, and C E D, every one of which will be the base a pertine of one of the straight lines, and its spex or opposite the ular point in the next; again upon the sides of the triangle, form other, but smaller triangles or polygons, as will be necessary for measuring the boundaries within each primary triangle, as shown in the preceditive examples, (Art. 27, 28.)

The advantages of this method arises the easiness in fixing a straight line almost to any distance, and over every obstacle, and the proof in the protraction which it affords, as the apex of every triangle upon the same side must form mother straight line; for it is evident, if either of the sides is measured shorter than the true distance, the apex will fall within the straight line, and if longer, will fall without it, and would require the singular coincidence of an error in both sides, the one shorter, and the other longer than either of their true distances to make this point fall upon the line, excepting in the case of the true distances to both. it happen that a river, marsh, or other impediment, obstruct the continuation of the measurements of any of the bases or distances between the apex of the triangles, as between b and c, still the data is sufficient, if the series upon the other lines AB, and EF, have been continued; for the triangles bde, ecE, upon EF, and the triangles A b a, a D B, upon A B, can be constructed upon their respective bases, and the apex of each be made to fall upon the line CD. Here proof lines are not necessary beyond those required for finding the dimensions of the Lands under measurement.

30. When a claim a which is lake, or marsh, which lies in the middle either in a single field of farm, through which diagonals as hitherto exemplified, cannot be measured, as ABCDEF, first fix a station pale G, and the other stations A, B, C, D, E, F in such a manner as G can be seen and measured from each; then as before measure the lines AB, BC, CD, DE, EF, FA, with the necessary offsets upon them, and also AG, BG, CG, DG, EG, FG, which will daish the dimensions of this field.

Protraction.—Draw the of the bases of the triangle formed by the station lines, as AG, which construct the triangle ABG, and conjoin to this the whole stries of the triangles BGC, CGD, DGE, EGF, GFA, the last of which, viz. AGF, will be formed after constructing EGF; for after joining AF, the space AGF if the whole is correct, will exactly coincide with the dimensions of this triangle; but if otherwise, some error must have taken place, either in the protraction or measurements.

31. If the obstacles in the middle of the ground be so posited that all the stations which require to be placed around the boundary cannot be seen from one point but from two, as A and B, the same mode of procedure may be adopted as in Art. 30, and exemplified upon this figure, and in the protraction, the same proof of the degree of accuracy will be found by the coincidence of the dimensions of the last protracted triangle.

The same causes for forming one or two points, may form three or even four or five points in the middle of the field, as ABCDE, by which, as in the figure, the whole field can be protracted.

32. When a wood only is the object of measurement, and suppos-

place the stations A, B, C, D, E, so as a measuring its boundary, by circumscribing with station lines; beginning at A measure the dimensions of the small triangle A i k, which will measure the angle B A E. In the same manner the triangles B a b, C d k, l m D, and g f E, will expectively measure the angles upon which these are formed.

Protraction.—Construct the triangle Aik, and produce Aito B, and Ah to E, at B construct upon Bass as the triangle Bab, and produce Bb as far as d, and mark at BC: upon Cd as a base, construct the triangle Cdk, and produce Ck to D, and upon Dl as a base construct the triangle Dlm, of which produce mD to E: now as a proof of the accuracy of the work, DE and AE should meet each other in E at their measured distances from A and D; and also, besides this coincidence, by marking from E the points g and f, the side gf should likewise exactly correspond with its measured distance, as this triangle measures the angular position of DE and AE.

We have already, in Art. 27, stated the limits by which this method of protracting lines should be restricted.

33. Is a road is required to be measured, fix the stations as A, B, C, D, E, at the different turnings, but in such a manner, as usual, that lines can be measured between them, which may either be placed upon the road itself, or upon the outside of it; as in this case, within the road. Beginning from A and measuring A B, the angular position of A B and B C is found by measuring the triangle a B b; also the angular position of B C and C D is found by marking out the perpendicular c d with the cross staff from 400 on C D, and finding

this 118 cell minimum for the BC produced. The same operation is again produced for the same state from DE the perpendicular ef, and measuring with the same state from DE the perpendicular ef, and measuring of till meeting the line of CD continued, which together with the other necessary measurements and offsets as shown upon the figure, will efford the sufficient data for planning the road AB CDE. The same measurements are perpendicular to any other crooked space of ground whatever, and canals or rivers, as represented upon the plate.

In the foregoing articles, there is given that which I consider as the best practice of measuring land with the chain only, and throughout, such necessary remarks and limitations to the several methods, for ensuring the greatest accuracy of which such operations may be capable; for as already observed (Art. 7.), such suppose the surface to be measured almost perfectly smooth and level, and as this can only be the case partially in whatever country, the deviations from the truth will be proportional as the circumstances depart from or approach to this condition. However, it must be allowed, that for the general purposes of business extreme accuracy is not always required, and therefore what is already taught in surveying may be made occasionally useful;on the other hand, the use of angular instruments, with the applications of Trigonometry as we shall hereafter treat, will afford the greatest accuracy, be much more expeditious than the above, and -applicable to every case, in many of which the use of the chain only is quite insufficient.

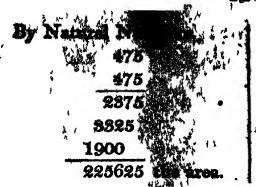

## 140

## OF SUPERFICIAL EXTENT OR AREAS.

34. The measure of superficial extent area, is denominated square measure, from a square containing the same area, or being equivalent to any other figured surface; as the square H may contain the same area of the irregular figure I, and if the side of the square H be equal to 1, then its area, and also that of its equivalent I, will each contain a square unit, or be equal to 1, which is one square yard, foot, or whatever other name the lineal measure of the side of the square is denominated: also, if the figure I be enlarged in its area, this is always expressed by the number of square units which it may contain.

35. Of the Square.—If the side of a square be equal to any number of a given lineal measure, as 2, 3, 4, &c. the area will be 2<sup>2</sup>, 3<sup>2</sup>, 4<sup>2</sup>, &c. that is, equal to the square of the quantity expressing its side; for if each of the sides of the square H', be divided into the same number of parts which express each of their measures, and the corresponding points of the opposite sides be joined, as in this case into four, then the whole area of the square is formed into 16 squares, each being a square unit of the side, which are equal to 4<sup>c</sup>. Hence the rule, multiply the side into itself, and the product is the area.

Example.—Required the area of a square whose side is 476.

By Logarithms.

475——2.6766936

2
225625=5.3533872

36. Of the Parallelogram.—The same may be shown of the Parallelogram as of a square, kir, dividing the length and breadth of the parallelogram K, as the side a into 5 and b into 3, then the whole area is formed into 15 square units, which is equal to  $5\times 3$ , so that the rule becomes multiply the length by the breadth, and the product is the area.

Example.—Required the area of a rectangle, the length of which is 366 and breadth 244.

By Logarithms.
366—2.5634811
244—2.3873898
89304=4.9508709

87. Of the Triangle.—Every triangle is equal to half of a parallelogram of the same base and altitude (Theor. 9.): therefore in the triangle A B C, the area is equal  $\frac{A \times B D}{2}$  or, multiply the base by half
of the perpendicular, and the product is the area.

Example.—Required the area of a triple 325 and base 536.

Also, if the three sides be denominated by a, b,

A, then 
$$\sqrt{\frac{a+b+c}{2}} \times \frac{a+b+c}{2} - a \times \frac{a+b+c}{2} - b$$

or, if S equal the semiperimeter (half sum of the  $A^2 = S(S-a)$  (S-b) (S-c) and  $A = \sqrt{S(S-a)}$  (S-a)

This useful formulæ may be easily derived algelowing manner \*.

$$a^{2} = \Lambda D^{2} + D C^{2} + 2 A D \cdot D C$$

$$c^{2} = D C^{2} + D B^{2}$$

$$b^{2} = A D^{2} + D B^{2}$$

$$and a^{2} + c^{2} - b^{2} = 2 D C^{2} + 2 A D \cdot D$$

$$therefore \frac{a^{2} + c^{2} - b^{2}}{2 D C} = D C + A D = a$$

$$and \frac{a^{2} + c^{2} - b^{2}}{2 a} = D C$$

$$but c^{2} - D C^{2} = B D^{2} \text{ and } B D^{2} a^{2} = 4 A^{2}$$

$$consequently 4 a^{2}c^{2} - a^{2} + c^{2} - b^{2} = A^{2}$$

<sup>\*</sup> For Geometrical Demonstration, see Robertson's Navigation, Vol. 7. p. 98; Leshie's Geometry, 6, 31, and Algebraical, Woolhouse's Frigonometry, p. 16; Simpson's Algebra, p. 264; and Leslie's Geometry, Note 49.

the squares of any two lines or numbers for their sum and difference, the last ex-

man which thus:
$$\frac{a^{2}-c^{2}+b^{2}}{4} = \frac{(a+c)^{2}-b^{2}}{4} \times \frac{b^{2}-(a-c)^{2}}{4}$$

$$\frac{a^{2}-c^{2}+b^{2}}{4} = \frac{a+c+b}{2} \times \frac{a-b+c}{2}$$

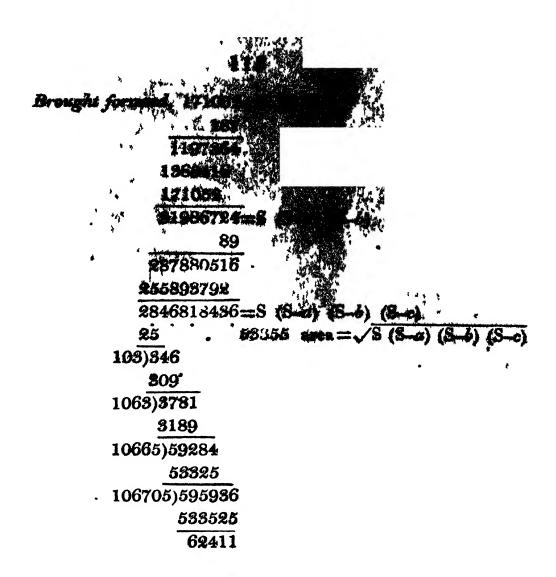

$$\frac{a^{2}-(a-c)^{2}}{4} = \frac{a+b-c}{2} + \frac{-a+b+c}{2}$$

$$\frac{a+c+b}{2} \times \frac{a+b+c}{2} \times \frac{a+b-c}{2} \times \frac{-a+b+c}{2} = A^{2}$$

$$\frac{a+c+b}{2} \times \frac{a+b+c}{2} - b \times \frac{a+b+c}{2} - c \times \frac{a+b+c}{2} - a = A.$$

uired the area of a triangle whose sides 276=a,

By Natural Numbers.

By Logarithms.

Log. 574—2.7589119
298—2.4742163
187—2.2718416

2)9.4543598
52855=4.7271799

which has any two sides the littlet, as A B and C D, is equivalent to the sum of two triangles of the littlet, each having one of the parallel sides for its base, and the littlete between the parallels their common altitude: as, the triangle A C B and C B D are together equivalent to the whole figure A B C D, and C c is equal to B b. Whence by (Art. 87.) C D+A B C C T B b = the area, and the rule becomes, multiply the half of the sum of the parallel sides by the altitude (their distance), and the product is the area.

Example.—What is the area of the rhomboid whose parallel sides are 376 and 298, and the distance between the parallel sides 135?

By Natural Numbers.	By Logarithms.

45495 the area.	I .

39. Of regular Polygons.—It the centre and angular points of a polygon be joined, as AG, BG, CG, DG, EG, FG, the whole figure will be divided into as many triangles as the figure has sides, and the sum of all the triangles is equal to the whole area of the polygon ABCDEF: now the area of each triangle is the side of the polygon multiplied into the half of the perpendicular (Art. 37.); as ABA

a 
$$\frac{G}{2}$$
 =area of ABG, BC× $\frac{b}{2}$ =B  $\frac{G}{2}$ =CGD, DE× $\frac{d}{2}$ =DGE, EF× $\frac{G}{2}$ =EGF, and  $\frac{G}{2}$ =AGF: but as every perpendicular from the centre upon rate of the sides is equal to the radius of the inscribed circle, they are the sides is equal to denominating the radius by  $r$ , the sum of the sides will be AB+BC+ $\frac{CD+DE+EF+FA}{2}$  Hence the rule for finding the area of any polygon is, multiply the side by the number of the sides, by half the radius of the inscribed circle, and the last product is the area.

Example.—Required the area of a hexagon, whose side is 230, and perpendicular from the centre 199.

By Natural Numbers.

But when the area of a regular polygon is required, there are seldom any other dimensions given more than the length of the side; therefore, to facilitate the calculation of the areas of these figures, writers upon this subject have prepared the following table of multipliers, by which the area of any polygon having its sides only given, can be easily found.

No. of Sides.			The second	M	ilt <del>i</del> plier.

40. Of the Circle. It a circle be in polygon of any manintroduction of sides of the ber of sides, and another polygon of twice former be also described touching the same trees, the perimeter of the last polygon will be less than the period of the first, and will touch the circle at double the number of process; and so the perimeter of every polygon will be less, and touch the firele in a greater number of points than any other polygon of less tumber of sides described upon the same circle; for a b, c d, e f, g h, as common to both of the perimeters of the polygons ABCD smalls bcdefgk, and bc is less than b B+B c, and de is less than c+c e, and fg is less than f D + D g, and ah is less than h A + A a: (for any two sides of a triangle are greater than the third) therefore a b+c d+e f+g k +b B+B c+d C+C e+f D+D g+h A+A a is greater than  $\overline{ab+cd+ef+gh+bc+de+fg+ha}$ : but the first sum is equal to A B+BC+C D+D A, the perimeter of the polygon of four sides, and the last is equal a b+b c+c d+d e+e f+f g+g h+k a, the perimeter of the polygon of eight sides: consequently by doubling the number of sides continually, the difference of the perimeter of the last polygon, and the circumference of the circle, may be less than any calculable difference, or the one be ultimately equal to the other. Hence the rule for finding the area of the polygon applies to the circle, which is, multiply the perimeter (circumference) by half the radius, and the product is the area.

Example.—Required the area of a circle whose circumference is 722 and radius 115.

Also, it being found that when the diameter of a circle is 1, its circumference is very nearly 5.1415926, and by the use of the above rule, and using 3.1416 instead of 3:1415926, we have 3.1416x\(\frac{1}{4}\)=.7854 the area very near: now, because the diameter of the circle and the side of its circumscribing square are equal, and the area of the circumscribing square being 12 (Art. 34.): the ratio very nearly of the areas of a circle whose diameter is 1, and its circumscribing square, will be as .7854 is to 12; therefore if the diameter of any circle be denominated by D, the following proportion is given: as 12: .7854:: D2: the area of the circle, or the rule is, multiply the square of the diameter by the decimal .7854, and the product is the area.

Example.—What is the area of a circle, the diameter of which is \$22.

41. Of the sector of a Circle.—The state of the sector of a circle, is to the area of the whole circumference: for sectors of the same circle having equal arcs are in every respect equal (Ax. 4); therefore, if a denominate the area of the circle, c its circumference; the area of the sector, and A B its arc, we have by proportion, c:a:: A B:s, or, axA B = s:

but as the radius of the circle is necessarily given in the dimensions of every sector, which call r, then

 $a = \frac{r \times c}{2}$  which expression of the area if substituted in the above formulæ,

it becomes  $\frac{r \times c}{2} \times AB = r \times AB = S$ , or the rule is, multiply the arc

of the sector by half of the radius, and the product is the area.

Example 1.—Required the area of the sector of a circle, the radius being 250 and the arc 366.

By Natural Numbers.

250 2000 250 45750 area of sector. By Logarithms.

250 Log.—2.3979400

183 ——2.2624511

45750=4.6603911

If the arc is given that the circumference, but of a different measure from the the radius, such as the common division of the circle into 360 called degrees, each of which is again measured by 60 subdivision malled minutes, and each minute into 60 parts called records, the above rule for finding the area of a sector, the arc of which is expected in degrees, minutes and seconds, will be altered thus: first find the area of the circle in parts of the radius, and multiply this by the manber of degrees in the area of the sector, which product divide by 360, and the quotient mill be the area.

What is the area of the sector, the arc of which is 50

degrees and radius 20.

4.7981809
360——2.5563025
174.583=2.2418784

42. Of the Segment of a Circle of the area of the sector having the arc as the segment by the last article: also find the area of the tangle which is formed by the chord of the segment and the radii, and subtract the last from the first when the segment is less than a semicircle, and the remainder will be the area: but the sum of these will be the area if the segment is greater than a semicircle.

Example 1. What is the area of a segment A D B E A, its chord A B being 199, its height D E 20, and arc 128.7\*.

To find the radius.

$$\frac{A E^2}{D E}$$
 = E F, by (Theor. 18.) and  $\frac{E'F+DE}{2}$  = C D the radius = 100.

128.7 the arc.

50 half of radius.

120 the chord.

6435,0 area of sector A C B D.

40 half of E C.

4800. area of A B C.

4800 area of triangle A B C.

1635 area of segment ADBEA

Example 2.—Required the area of the opposite sogment A E B F A, the chord A B being 120, its height 180, and arc A F D 499.5.

To find the radius.

$$\frac{A E^2}{E F}$$
 =D E by (Theor. 18.) and  $\frac{E F + D E}{2}$  =C E the radius=100.

499.6 the arc.

120 the chord.

50 half of radius.

40=DC-DE

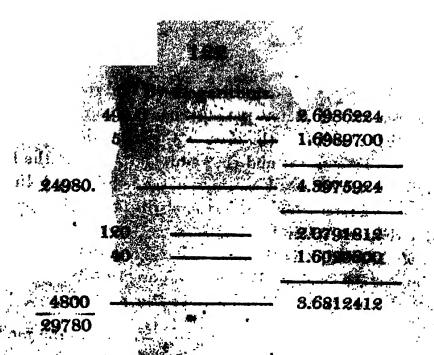

24980,0 area of sector.

4800 area of triangle A B C.

4800 area of ABC.

29780 area of segment AEBFA.

\* I have given in these examples the dimensions of the segment only, as it is this we can alone contemplate in actual measurement, but not the radius of the circle, which is inaccessible in most cases of practice.

43. Of the circular ring or space between two concentric circles.—
The area of the circular ring ABCDEF, is evidently the difference of the areas of the two circles ABC and DEF, which is expressed by BC\*\*.7854—EF\*\*.7854, or BC\*—EF\*\*.7854: but as BC\*—EF\*=BC+EF\*BC—EF the area of the ring will be equal to BC+EF\*BC—EF\*.7854; or, multiply the sum of the two diameters by their difference, by .7854, and the last product is the area.

Example.—Required the area of the circular space between two circles, whose diameters respectively are 100 and 200.

200 100 300 100 30000 .7854 22562,0000 the area.

44. Of the Ellipse.—The ellipse is the projection of a circle by parallel

183

lines drawn from one plane to another. The cal plane being of to the circular one, as the section of section or circular roller, when cut perpendicular to its axis is a circle, but to blique is an ellipse; from which it will appear that the ellipse is described by lines drawn paral. lel to the axis of the cylinder upon its surface, and perpendicular to the right section or clade, and that the diameter perpendicular to the plane of inchuation, or shartest diameter of the ellipse, is constantly equal to the diameter of the circle: also, every parallel drawn to the shortest diameter of the ellipse, is equal to the same projected upon the circle: for if the ellipse E G F H be the projection of the circle A C BD, upon another plane oblique to it, then F is equal to A B, for both A B and E F are diameters of the same collinder: also, if e f and a la are the projections of a b and c d, then e f is equal to a b, and a h is equal to cd; because e f passes through the cylinder at the same distance from the axis as a b, and g h the same as of c d, so that e f is the chord of the same arc'as a b, and g A of the same as c d. (Ax. 1.) Consequently the alteration made upon a circle by this projection. can only be the elongation of its figure in the direction of the plane of inclination, and which causes the formation of the ellipse. It will appear, after the same manner, that the circumscribing square of the circle, when projected, will be a rectangle circumscribing the ellipse having its breadth equal to the shortest diameter, and its length the longest diameter: whence we have, as the area of the square a b c d is to the area of the circle A C B D, so is the area of the rectangle efg & to the area of the ellipse; or, as 12:,7854, so is the area of the rect. angle to the area of see ellipse, from which proportion this rule is derived, multiply the street and longest diameters together, by the decimal .7854, and the last product is the area of the ellipse.

è

<sup>\*</sup> The axis is a straight line passing through the middle of every diameter of the cylinder.

There now treated of the areas of simple figures, we shall, betions proceeding upon the methods for finding the superficial extent of lands, notice the different measures in which this is found.

The Lineal Measures, by which the dimensions of land are taken, varies in different countries, as with us the lowest measure is an inch, from which are raised all the other greater measures, as the foot, yard, and mile. In all parts belonging to Britain the denominations are nearly the same; but the respective values vary according to the ancient standard of each country, as will appear from the following Tables.

```

Note. Although it appears in the Table of Scotch Mean that the chain is 74 Scotch feet, yet mostly throughout all Scotland it is used only 74 English feet, but so far as I can learn there is no other authority for this reduction of the old measure, than being the custom of Land Surveyors, which likely has arisen from considering only the number of feet, and not the difference of the national measures.

# OF CALCULATING THE SUPERFICIAL EXTENT OF LAND.

46. It has been shewn that seldom the boundaries of land can be directly measured, but is done indirectly, by station lines, and offsets; which form two or more different figures upon the ground. As the first are commonly the sides of a triangle, and the other that of a trapezoid, it is evident, the area of the field can easy be found by the respective rules for these figures, when using the measured dimensions only.

### CO STREET PROPERTY

Example 1.—To find the area as mental by offsets, within the boundary a A E e, and station line a F E e, in English measure.

boundary a A E e, Triangle. (Art.	and station line a F Ke, in	English measure.
	87.) AF × aF=	-
The	AF+bg,xFam 18	$5 + 25 \times 120 = 4800$
Taperoids,	bg+ch ×g 4 21	5 + 17 × 110= 4620
(by Art. 38.)	$ch+di \times hi=17$	$7 + 30 \times 70 = 3290$
	$d i + \mathbf{E} k \times i\mathbf{K} = 30$	$0 + 10 \times 213 = 63900$
Triangle,	$\mathbf{E} \mathbf{K} \times \mathbf{e} \mathbf{K} =$	$10 \times 15 = 150$

If the line A E is curved, which is very often the case, the contents will be more than the truth if this is convex, but less when concave, towards the station lines upon which the offsets are taken, by a small segment which lieth between the boundary and a straight line if joining the extremities of these upon it, as the segments A m b and C n d in the little whence it appears, that the nearer the offsets are taken to one mother where the boundary is curved, the area derived therefrom will be nearest the truth.

<sup>\*</sup> It is here the same to divide the sums of the trapezoids and triangles by 2, as taking the half of each separately, according to rules of Art 37 and 38.

Note.—Any sum of aguare links is parily reduced to agree, &c. as in this example of English measure, by cutting off upon the right hand 5 figures, or dividing by 100,000, the number of square links in an acre, and those upon the left will always express the acres; in the same manner, after multiplying the right hand figures by & for re-40 for perches, and 36 for yards, we shall have the left hand figures pressing the acres, roods, whiches and yards; for the right hand he are constantly the decimals of these measures, which after having explained, we need not repeat this operation in the following examples.

Example 2.—Require the area of the triangular field A B C, in Scots measure.

Find the triangle a b c, by the 2d Ex. of Art. 37. = 70324 sq. links.

Tind the triangle 
$$a$$
  $b$   $c$ , by the 2d Ex. of Art.  $37. \pm 70324$  sq. in  $10 + 20 \times 420 = 1260$ 

Trapezoids by Art. 38.  $17 + 25 \times 345 = 14490$ 
 $12 + 14 \times 475 = 17100$ 
 $10 \times 31 = 310$ 
 $20 \times 23 = 460$ 

Right angled triangles, by  $17 \times 27 = 459$ 
Art. 37.  $25 \times 32 = 800$ 
 $12 \times 40 = 480$ 
 $14 \times 30 = 420$ 

3 Roods, 21 Falls, 4 Ells, = .88213 sq. links.

2)35779 = 17889

In the above example there are some dimensions more than merely for constructing the figure, as shown by the additional measurement of 30. 31. 23. 27. 32. 40. which are necessary anding the area of the small spaces left out on the angles by the effects, and which

more than two, these form the sides of the more great triangles, from which, offsets to the angular points to the field, are measured perpendicular by a cross staff.—This instrument I have already we should not be used for long lines, when any degree of accurment quired, and it would be quite unaccessary to give the follows example, were this not to shew a bad practice.

Example 5.—Find the area of each of the three fields, within A h ik B i from the following dimensions, made upon only one leading line A B.

$$A c = 140$$
  $c h = 345$   $c d = 325$   $d l = 326$   $d e = 40$  Offsets  $e i = 403$   $f m = 26$   $n f = 24$   $g k = 318$   $f g = 264$   $g B = 116$ 

Area of A h m l, 1 acre, 2 roods, 10 perches, 22.7 yards. 1.56644

<sup>\*</sup> When two unequal quantities are to be multiplied by the same quantity, as 140 and 401 by 345, the result desired will be found by adding the two unequal quantities together, and multiplying by the common multiplier.

By the above method it is almost constantly necessary to produce the perpendiculars across one, and sometimes two fields to the opposite angle, which by reason of the imperfections of the cross staff, renders such measurements quite unfit for constructing a correct plan; besides it can only be used on open and very level lands; for if otherwise, there will frequently happen interruptions to the measurements, if not made wholly impracticable, of those continuous to the measurements, from intervening trees, houses, and swelling or sloping grounds, likewise by which the point of intersections upon the leading line cannot be directly found. Also whatever carried is upon the boundary between the perpendiculars, and as this incomeave or convex towards the leading line, will cause an error of deficiency or excess by the segment convinced upon it; so that by the method all the boundaries would require to be straight lines between the perpendiculars; for it is practice, can take the time of making the offsets so near each other to avoid this error, as can so exally be done, when the station line is run near the boundary. But with all these disadvantages, I have no doubt there are practitioners who may set forth ways and means of overcoming, or at least presume to render such operations are sufficiently accurate, however, unscientific, and slovenly it may appear to others \*.

48. Before we can give a rule for finding accurately the respective areas of two or more fields together, find a series of triangles covering the lands, and the dimensions of which will also construct the plan as shewn in the last section, it is necessary to demonstrate the following theorem, which I have reserved for this place, as particularly applicable for the purpose.

Theorem—Triangles which have a common angle, are to each other as the rectangles of their containing sides.

For let A B C, and D B E be two triangles, having the same common angle at B, and denominate A B = a A C = b D A = c A E = d and the perdendicular E E = p,

then we have by Theor. (9). 
$$\frac{a \times p}{2} = \text{area A B E}$$

$$\frac{c \times p}{2} = \text{area A D E}$$

<sup>\*</sup> Those who wish to see several examples by the cross staff, may consult Ainslie's Landsurveying, page 28, Crosker, Nisbet, &c.

therefore area B B E : area B D E :: a : c in the same manual B D C : area B D E :: b : d

and and A B E : area B D E : : a d : c d

area B D C : area B D E : : c b : c-c'

wherefore area B B C : area B D C : : # d : \* 5

and consequently must area ABC : area BDE : a & ; c d

Cor. 1.—Hence triangles having one common angle are as the difference of the squares of the half sum, and half difference of the containing sides, for  $ab = \frac{a+b}{2}$ ).

Cor. 2.—Also similar triangles are as the square of their homologous sides.

for A B C: A D E: ab::cd

but a:c as b:d for D E and B C are parallel. (Theor. 16.) hence A B C:A D  $E::a^{c}:c^{c}$ 

Cor. 8.—And all rectilined figures are as the squares of their homologous sides: for dividing these each into similar triangles, viz. A, B,C, D, E, and A', B, C', D', E'; and calling the homologous side or rach triangle, a, b, c, d, e, and a', b, c', d, e': by Cor. 2.

 $A : A' : a^2 : a'^2$ 

 $B : B' : b^* : b'^*$ 

 $C : C' : c^2 : c'^2$ 

 $\mathbf{D} : \mathbf{D}' : d^2 : d^{\prime 2}$ 

 $E : E' : e^2 : e'^2$ 

and  $A : B :: a^{\epsilon} : b^{\epsilon}$ 

 $A:C::a^2:_{\sigma}c^a$ 

 $A:D:a^{i}:d^{i}$ 

 $A : E : a^2 : e^4$ 

wherefore  $A : a^2 : A + B + C + D + E : a^2 + b^2 + c^2 + d^2 + c^2$ 

and A+B+C+D+E: A+B+C+D+E: a'+b'+c'+d'+e': a'+b'+.

c''+d''+e'
and consequently A+B+C+D+E: A+B+C+D+E: a': a'
: b': b''
: c': c':
: d: d''
: e': e'':

By the Theorem we have the following Rule for finding the angular portion of the area of any triangle, which is divided into two parts by a straight line, when the distance of the intersecting points of this line, upon the two sides from the angular point are known Multiply the area of the whole triangle by the distances of the intersecting line upon the sides from the angular point, the product of which divide by the product of the sides, and the quotient will be the area of the angular portion.

Example 7.—Calculate the respective areas of the two Fields, A and B.

To find the triangle a c d.

```

                                                 1.3\overline{0504} = 1.1.8.8
             Total area of Field B,
```

After the same manner the suspective areas of three fields A, B, C, may be calculated, as Field by the figure is equal to ae f + ac d - fci, Field B = ag if ci - aef - ch k; and Field C = ch k + abc - agh; as adding the offsets belonging to each as shewn above.

Where it has been necessary to measure between any two of the sides of a triangle as f, it is devious that the area of the triangle f is can be found from its three lates now given, instead of using the above rule.

There are cases in which it may be necessary to take some dimensions besides primary triangles; but these will vary according to the relative position of the fences with the sides or station lines, as in the three fields D, E, F, where the measurements g f, g h, f h, are additional for finding the area of the small triangle g h f.

Field 
$$D = abi + ak + ghf - elk - cif$$
  
Field  $E = cib + cif + chk - ghf$   
Field  $F = leh + cek - chk$ 

When besides the primary, triangles, other lines within these are likewise measured for delineating the boundaries of a number of lots, areas or buildings, by which the triangles are divided into irregular polygons; the above rule in this case is not applicable for finding the respective area of each, without such be resolved into triangles, and the additional measurements as last shewn are also made, whereby the whole figure is divided into parts of the triangle, fit to be calculated as above. For this purpose it is not always necessary to make these, actually upon the ground, but upon the plan after delineated by the field dimensions, when such additional lines may be drawn and measured by the scale, which with those actually measured upon the ground, the respective areas can be found.

49.—Hertofore I have only shewn the without of calculation of areas by Natural Numbers and Logarithms that as the first causes a multiplicity of figures both tedious and limit to error, and the other is not applicable for adding the products of quantities, which is a continual operation in the calculation of areas. I have here following, given another method by the use of a Table of quare Numbers, which is peculiarly applicable to the last purpose, and equiring only in the actual operation for finding the sums of the products of any number of pairs of multipliers, the addition and subtraction of two sums. For facilitating this method of calculation, and as particularly useful to Landsurveyors, I have calculated the following Table of Square Numbers from 1 to 2000.

Table of Square Numbers from 1 to 2000.

Application of the Table.

If it is required to fine the stars of any number below 200, as 169, this is always found to be as 28561, after rejecting the two cyphers upon the right hand the same is found opposite No. 16, in col. 9, and of every number below 2000 the square is found in the column of the number of wight hand figure, and opposite the number expressed by the remaining figures upon the left, as the square of 1786, in col 6, opposite No. 178 is 3189796. But if a decimal is attached to the number required, as 1786.8, the following rule may be used. Add to the square of the integral number, the tenth part of the product of the integral number and twice the decimal, also to which add as a decimal the square of the decimal, as

> the square of 1786 by the Table is 3189796 1786 × 6 1071.6

If 17863 be required, the operation becomes the same, with the exception only of the decimal point which is now rejected, as 319086769 will be the square; --- whence it appears, with the use of the above tables and rule, we always can find the square of any number below 20000.

Example 1.—Required by the table of square numbers to find the product of a b a = 348 and b = 236.

By Cor. 1. of (Art. 48.)  $a b = \frac{a \times b}{2}$   $\left(-\frac{a-b}{2}\right)^2$  wherefore the operation of this example.

$$\left(\frac{a+b}{2}\right)^2 = \left\{\frac{348}{236}\right\} \frac{584}{2} = 292$$
 the square of, by Table = 85264  $\left(\frac{a-b}{2}\right)^2 = \frac{112}{2} = 56$  the square of, by Table =  $\frac{3136}{82128}$  and product of 348 × 236 as required.

Example 2.—Required by the Table, the sum of the products of  $247 \times 245$ ,  $236 \times 458$ ,  $369 \times 169$ ,  $235 \times 174$ .

Sum of quired	products re- ]	271854						-

It appears in the above, when the sum is odd, as 409, the difference must likewise be odd, and the decimal .25 is produced equally on both sides, which therefore may be rejected in the additions of the operation. By taking the squares of the sums and differences, instead of the half sums and half differences, and dividing the difference of the sums of these squares by 4, will shorten the above operation: or by using both, the one may be the proof of the other \*, as

<sup>\*</sup> It is satisfactory to observe, that the greatest confidence may be placed in the above table, as these have been fully proven upon the proof sheet from the press, so that the proof only now required, is upon the operation of addition and extracting these squares from the tables.

The sum of the products as before.

than those for calculating the area of lands, from this it is the common practice in extensive surveys, to take such dimensions that are only necessary for planning, and afterwards by the scale from which the delineation has been made to find new dimensions, whereby the superficial area is more conveniently calculated than by the first. It is evident, by this method, the area of the superficial extent depends wholly upon the accuracy of the delineation made by the first dimensions; the manner of taking which, has been sufficiently shewn under the last section, so far as regarding surveys to be made with the chain only.

A common method of calculating the from the delineation, is by dividing each field into triangles. The the scale measuring the base and perpendicular of each triangles and taking the collective contents for the area of that left of the scale measuring the collective contents for the area of that left of the scale measuring taking the collective contents for the area of that left of the scale measuring the collective contents for the area of that left of the scale measuring to the scale measuring to the collective contents for the area of that left of the scale measuring to the scale measuri

When one or more of the sides of the side is curved or crooked, as the side A B, it is necessary to draw a straight line, making equal areas on both sides between it and the crooked line and calculating the field as above, after having taken the dimensions upon this straight line as its boundary.

The manner of drawing a straight line so as to contain equal areas on both sides of a curved or crooked line is sometimes by surveyors in practice, done by judging with the eye, till the space upon each side of it appear equal; but where accuracy is desired, the following method should be used.

If it is required to straight the crooked line A B C by drawing A D from the point A, to meet another line C D which is at any given angle to B C; first draw through B, the straight line B D parallel to A C, and meeting C D in D; then join A D, which will be the straight line required; for the triangles A B C and A D C are equivalent by Cor. 2. Theor. 9.

This problem may be applied generally, and to any crooked line whatever; as let 8. 7, 6, 5, 4, 3, 2, 1, I, be one of the sides of a field which is required to be straight by a line drawn from the point 8, and to cut the next side, the direction of which is I K. First cut I K, by a line through 1 parallel to 2 I, and mark this intersection 1, next cut I K, by drawing a line through 2; and a parallel to 3. 1, and mark this intersection 2, again through 3, and parallel to 4. 2 cut I K, and mark the intersection 3; also make the

intersection 4, through 5, and 5 through 6, parallel to 7. 4; and 6 through 8. 5; and lastly join 8. 6, which will be the line and through 6. 8. 5; and lastly join 8. 6,

If the line represent A B C D E F, it becomes first necessary in this case to the lines by the eye, but each the lines are considered with the curve, as to avoid any sensible error and B, B C, C D, D E, E F, and afterwards resolving those into the straight line A H, by the above method.

51. The second method of calculating from the delineation is by drawing parallel lines at equal distances from each other covering the whole field, and upon the extremities of each parallel space, straightening the boundary by a perpendicular to the parallels; then taking the lengths of each space, and adding them together, the sum of which if multiplied by the common breadth will give the area; as let the area of the field A B C D be required.

In laying off the parallel it will save the trouble of straightening upon one of the sides, if these are drawn perpendicular to that which is a straight line, as D B, by which the side A C, is only necessary to be straightened upon each parallel space, by lines drawn parallel to DB; but as it is common that the angles made by the fences are not often right angles, there will be angular portions both taken in and left out by the outermost parallel lines, which must be calculated separately, and added or subtracted to the collective area of the parallel spaces as the position of such requires, as the triangle C D D' must be subtracted, and triangle A B B' is to be added; as

\* By thus numbering the angles both upon the crooked line, and I K, the crioi of not drawing through the two angles is easily avoided, for this is always the number lying between the number upon I K, and that upon the crooked line, as the line of a volthrough 4 is parallel to 5 and 3, and the intersection of this is also 4 upon I k.

If it is found after the parallel lines are drawn that the boundary is a straight line between each. The plowing formulæ may be used for calculating the area of the parallel spaces, where a, b, c, d, e, f, denominates the respective lengths of the parallel lines, D their common distance, and A the collective area.

$$A = \left(\frac{a+f}{2} + b + c + d + e\right) D \text{ as } a 245$$

$$f 284$$

$$2)529$$

$$2(34.5)$$

$$b 272$$

$$c 236$$

$$d 306$$

$$e 270$$

$$1348.5$$

$$D 100$$

or calling the sum of fourth, sixth, &c. B, an

Area = 82133,00

putting D for the common distance is, before \*, as

Required the area of the field A B C D, measured by equidistant parallels.

52. One of the best methods of calculating areas from the plan is after straightening the irregular boundaries of any figure, as ABCDE is to draw lines through every angle parallel to one of the sides, as BBD 'CC' all parallel to AE, and afterwards intersect these by a perpendicular line, either within or without the figure: then by measuring the lengths of each parallel line within the figure, as AE 356,

<sup>\*</sup> This is not a perfect rule but a very near approximation. See Dr Hutton's Mensuration, page 374

B B' = 568, D D' = 296, and on the percenticular their distance ab = 246, bc = 96, cc = 34, dc = 34, dc = 34 and dc = 34 are dimensions of the trapezoids A B B' E, and B D B A Calculated by Art 48 stand as follows:

This method has considerable advantage in practice, over the methods of triangles, by the facility of proving the dimensions, and of equal parallel lines in having fewer; as the sum of the heights of the trapezoids, and the whole line and should be exactly equal; next by taking the half length of the first measurement of each parallel line from the scale, this should step exactly twice its respective length, which together affords a complete proof of all the scale dimensions. Whereas in the method of triangles the perpendiculars of each are upon their respective bases, and may be proven by a repetition of the same measurements, but without a proof in a collective sum as in the above.

It will appear obvious in the calculation of areas by the scale, the fewer dimensions which can be used, and these proven collectively instead of separately, that the results will be nearest the truth; for there are two sources of error when calculating by the scale in the way of perfect agreement with the true content as would be derived, if possible to calculate the same from the dimensions by which the plan has

been constructed; the property of the property of the lengths of the property of these means of error may be overcome by proving an acree the perpendiculars collectively with an equal divided scale; but the other will always arise to a degree, and especially the more lines which are employed in the calculations.

Besides the means of error above stated, there is a third peculiar to calculations made upon proces, which is the expansive or contracting power of this substance by moisture or dryness, which may alter the whole surface of the plan less or more as it is exposed to the extremes of either of those states of the timosphere; which circumstance points out to all surveyors the necessity of having an office not in the least liable to damp, but which will be in nearly an equal state of dryness throughout the year. This also shows the necessity of having one line marked out to the whole length of the same scale by which the plan is delineated, and upon the same sheet, to which an exact reference of the expansion or diminution above or below the original scale may be always made.

53. In Art. 4, I pointed out the method of finding the chain error, and now answerable to which I have calculated the following Table for finding that correction in superficial measure for every acre.

TABLE

Shewing the Superficial Correction with the state of the Chain error, from one-tenth of an inch to four the state of the Chain error, from above the length of the Same of the Chain.

Teample.—Required the true tent, of which the calculated contents are 46 ... 3 ... 10, here measurement made with a chain 74 feet 2 inches in length in scots Manager.

Celculated contents,

46 : 3 : 10

Superficial correction of the Table of Scots Measure for the chain error of the ches plus 74 feet upon every tone is 1.044 falls, which calculated by propor-

tion for 46 : 3 : 10— is

0:1:8.87.

True extent,

47:0:18.87

Example 2d.—Required the true extent, of which the calculated contents is 23: 3: 35 from reasurements made with a chain 1 inches minus of 66 feet in English Measure.

Calculated contents,

A. R. F. 35

Superficial correction by the Table of English Measure for chain error 15 inches minus of 66 feet, is upon every acre, .482 fall which calculated by pro-

portion for 23 : 3 : 35 — is

0:0:11.55

True extent,

23 : 3 . 93 45

In the case where the chain entire is greater than in the above Table, the following formulaes may be considered calculating the superficial correction, after denominating the standard length of the chain by a, the chain error by b, and  $\mp$  C, the superficial correction, as the chain error is below or above the standard.

$$-C = 20ab + 10b + C = 20ab - 10b$$

Example. Find the superficial correction for the chain error of 5 inches, or .518 links plus, Scots measure.

$$a = 100 \text{ links.}$$

$$\frac{20}{2000}$$
 $b = 518$ 

$$\frac{1086.000}{2000}$$

$$10 b^2 = 2.689$$

1038.683 Superficial correction in square

links to be subtracted for every scra

If the same chain error be minus, then

$$a = 100$$
 links,  
 $20$   
 $2000$   
 $b = .518$   
 $1036.000$   
 $10b^2 = 2.683$ 

1033.317 superficial correction in squaré

links to be added for every acre \*.

\* \* Observe in laying out ground with a short Chain or error minus, as  $74-22_5$ , the quantity wanting of the true area is of the same sign of the Chain energy, as in this, 1.041 falls, or 20  $ab-10b^2$ , and if the contrary or  $75+\frac{1}{2}_{55}$  the excess land of will be 1.044 or 20  $ab+10b^2$ .

In the feregoing when giving the rules for the calculation of areas, I omitted purposely the standing the areas from the sides and angles together, but which the fully exceptified under Trigonometry.

58. The following states such which their respective titles explain, and are of constant to the practical Surveyor.

Shewing the corresponding Links, in any number of Roods, and Perches or Falls, from one Fall or Perch to one Acre.

54.—It will now separate that for taking the measurements of any considerable extent of the life more mavenient to make only those necessary for constructions with the measurement by the methods given in Art. 52, find the measurement of the fields or plots as marked out either by the medicies of the land or its fences. But more particularly to illustrate the advantages of this mode of finding the areas, we shall all the following actual survey of a Villa and Farm, the plan of white was wholly constructed from chain measurements and offsets out.

As upon the figure, the primary triangles measured were, A B C, C B D, C D E, E D F, E F C, F G H, D L I, L I K, and the quadrilateral F I K H. The point E was upon the straight line C G, by which the three triangles D E, E D F, E F G, were comprised in the quadrilateral C D F G. The secondary lines besides the primary triangles for completing the were a F, b c, d e, f g, and h g, all within triangles D E, with within C B D.

From the distribution of the principal triangles, the sides of these afford sufficient distributions without a plan the whole area of the lands: but this with the subsidiary measurements, are not enough for calculating the respective areas of all the fields, without the addition of a number of others, or Scale measurements. Hence it is manifest that for constructing a plan only of many fields, the measuring may be much less than if to afford data for calculating the area of each field respectively: for by the shortest method possible, had the different plots of this plan been measured so as to have given data for calculating each field, this would have required to have measured every one after the manner of Art. 46. Ex. 2 and 3; or at least by Art. 48, Ex. 7 and 8.

As upon the plan every marked make fields together, should afford data in the actual measurements for charactering the whole area from the series of triangles covering the table, by which a correction is afforded for the scale make ments of special in the collective contents of the last should always agree very marry with the first, and when this is obtained after having the acturacy of the actual measurements proven by proof lines, then acturacy of the actual measurements proven by proof lines, then wan be no doubt that the results of all the parts caliculated by the scale are true.

If we now take a view of the different methods of surveying with the chain only, which I have heretoror exposed, it is very evident for to obtain a complete verification of all the operations with the least labour, that a delineation of the lands is always indispensable; that is to say, when the extent is hand the imple cases (at A we can construct the plan with a great deal that which is requisite to find the while this at the same time will total area, which must be always and the are verified upon the plan by ment lines in the ments of the plan, with the calculations therefrom, may be always the simplest, and a complete verification obtained by their collective contents agreeing with that of the primary triangles; whereas, were each, field measured so as to afford data for calculating the areas severally, this would require in the event of making a calculation by one diagonal, another at least with the proof lines to verify it, so that this method under every circumstance would cause many more actual measurements than the above, and two calculations from different data before the results could be considered true.

<sup>•</sup> The proof lines are not shown upon the figure, but only those necessary for constructing the plan.

• 2 A 2

What is above advanced, where clearly the bad practice of the method of measuring with the chair staff as exemplified in Art. 47, and in the work appeared to therein, for in this method, proof lines cannot be make so us to allere data for two different calculations, but its accuracy depending wholly upon the first measurement alone, and without any varification whatever upon this; therefore whatever errors or omissions have been committed in the measurements, these cannot be corrected.

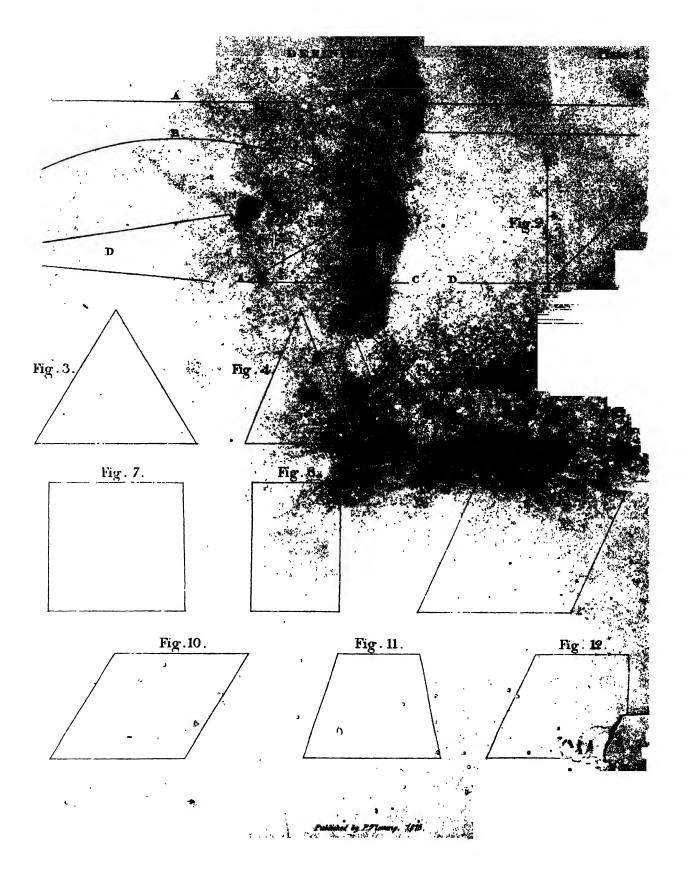

## ERRAMA.

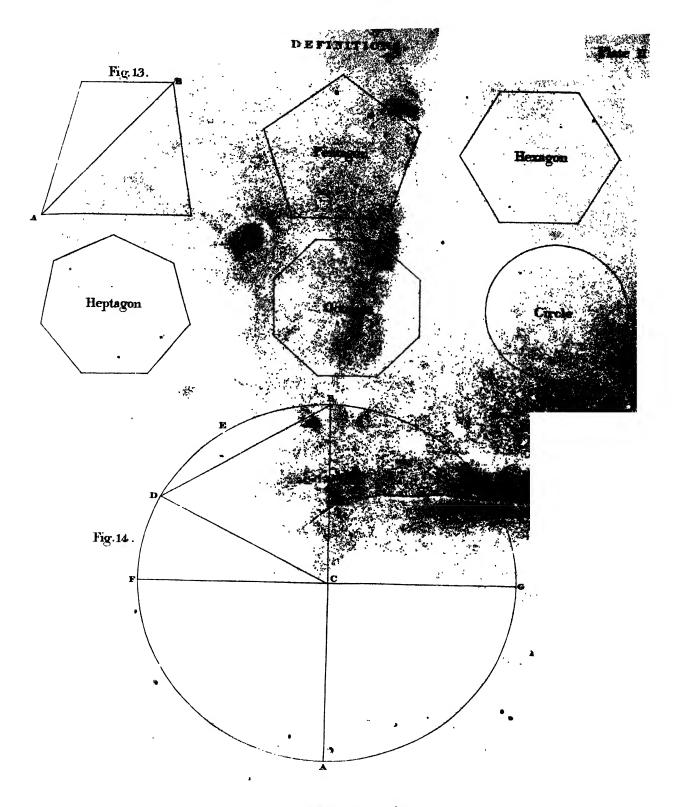

```
Page 5, line third from the top, for DFF, read D, E, F.
             7, line third from the bottom, for D L. read D F
          13, line fourth from the top, for bisect read trisects !
          14. line second from the top for A B C, read A, B, C.

16. line third from the top, for A O, indefinitely and ting, read A O indefinitely, cutting.

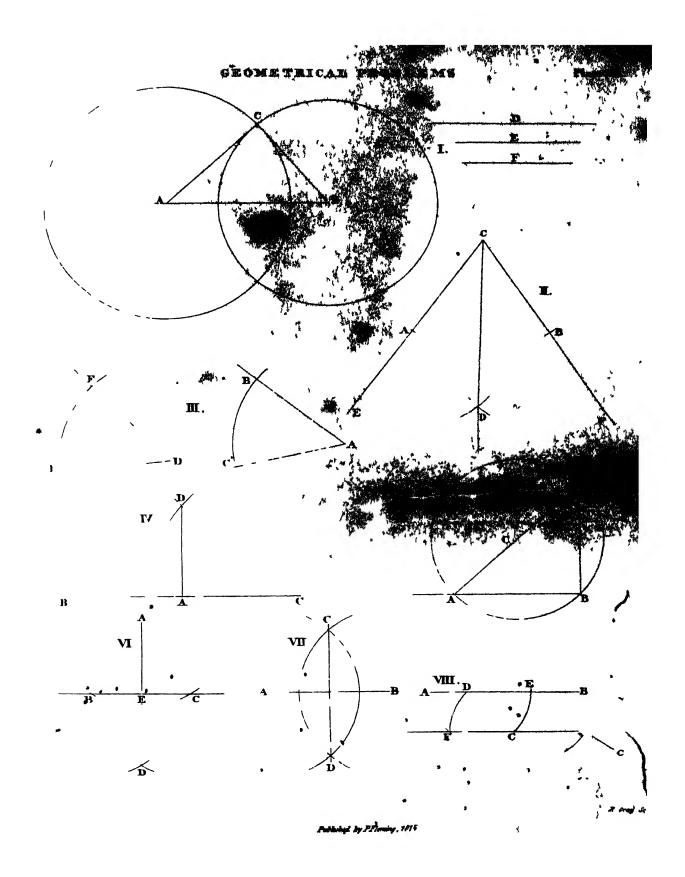

16. line tenth from the top, for circumference recommended in the circumference of the circ
          22 line ninth from the top, for b. c. a. e. f. gi read b. c. d. c. f. g.
          1b. line fourteenth from the top, for A B, read A D 27, line eighth from the bottom, for and is partilel, read and F K is parallel.
          32, line reventh from the top, fr A I I', read A I.
            16. line seventeenth from the top, for KEN, read FNK.
           Ib line twentieth from the top, for A LM B and the, read A L M B with the Ib. line trenty-secult from the top, The C L M, C L M. 50, live at bottom, for 42547 read with 7
             Il line at lottom, for 1 96 1, read 17621.
            55, line unicteenth from bottom, for 11930, read 10830.
           66, line twelfth from bott mi, for 499, read 588
            68, line north and tenth from bett m, for
           79, line elementh from the top, for 8.88,
           8 , line at lattern, for 1) I read DP.
           90 Art 9 for theme, for 1 K read F 1 DE.
            98, In effect the letter, for 95 rd 42, read 195 and 142.
         100 In eleventh from to top, for A C read A c 105, line fronth from the b tiom, for a D B, read a t B. 115 line there from the top, for $75, read 7.
         1 8. lim mith from the lettern, for 280 read 330.
         1'9 line's nthe from the top, for 7, read b.
            Il line see ith from the bottom, for 4816, read 6204.
             It has fourth free the lottom, for 18278, read 1966.
             1b. lim second from the bottom, for 91 9, read 9833.
             Il. bettem line, for 1 90504=1-1 88, read 1 31198=1.1 99.
         140, Inc fi teenth from the t p, for elk, read clh
          146, time t nth from the bett m, for 1763, read 1786.3.
             I. line second from the bottom, for \frac{a \times b}{2} \frac{a \times b}{2} real \frac{a + b}{2})
          150, two lines at the top, sead intersection 4, through 1 and parallel to 5.3; and 5 through 5 parallel to
                             6.4; and 6 through 6 parallel to 65, and 7 through 7 parallel to 8.6; and lastly join 5.7.
           157, lene such and seventh from the top, for 20 1 b-10 b2 20 a b-10 b2 20 a b+10 b2
              Ib. line fourteenth from the tep, for subtracted, and added.
```

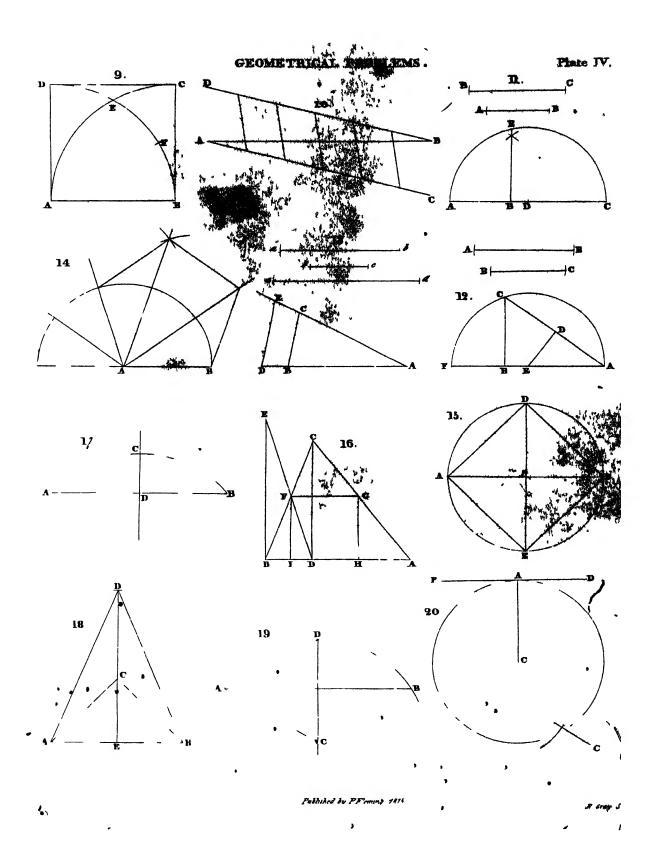

Ib. line of the from the bottom, for added, read subtracted.
